$$\begin{aligned}&\frac{d^2u_{11}}{dz}+6j\beta_qa'\frac{du_{11}}{dz}\\&\quad-9\beta_q{}^2\left[a'^2(1+b'^2)\frac{|m|^2}{4}-b'^2\right]u_{11}\\&\quad+j\beta_qa'\frac{3m}{2}[1+3b^2]\frac{du_1}{dz}\\&\quad-9\beta_q{}^2\frac{m}{2}[a'^2(1+b'^2)+b'^2]u_1\\&\quad-9a'^2b'^2\beta_q{}^2\frac{m^2}{4}u_1{}^*=0.\end{aligned}\tag{6}$$

The asterisk indicates the complex conjugate of a quantity and the assumption $(a'\omega_q/\omega)\ll1$ has been made. Eqs. (5) and (6) can be integrated by standard linear methods using the operator $d/dz=\beta_q\mu$. There will be eight waves propagating in this system. An approximate solution for the case of a thin beam $(a'=b'=1)$ and for small pump amplitudes, $|m|<1$, is given as

[3] A. Ashkin, T. J. Bridges, W. H. Louisell, and C. F. Quate, "Parametric electron beam amplifiers," 1958 WESCON CONVENTION RECORD, pt. 3, pp. 13–22.

$$\mu_{1,2} \approx \pm j6.0$$
$$\mu_{3,4} \approx \pm j2.0$$
$$\mu_{5,6} = 0.375\,|m| \pm j1.25\,|m|$$
$$\mu_{7,8} \approx -0.375\,|m| \pm j1.25\,|m|. \qquad (7)$$

More exact values of the propagation constants are shown in Figs. 1 and 2 respectively for a thin beam and a beam of finite thickness. The wave amplitudes can be calculated by using the boundary conditions that the signal is initially excited in the beam as a pure single space-charge wave and that the initial upper sideband velocity is zero. It can then be shown that only the growing or declining waves are appreciably excited. Gain can be obtained by adjusting the pump phase to $\Phi=\pi/2$. The velocity wave amplitudes for a thin beam are then described as

$$u_{\mathrm{I}} \approx 1.05 \cos\left(1.25\,|m|\,\beta_q z - 17.84^\circ\right)$$
$$\exp 0.375\,|m|\,\beta_q z \exp -j\beta_e z\left(1-\frac{a'\omega_q}{\omega}\right) \qquad (8)$$

$$u_{\mathrm{II}} \approx 1.822 \sin\left(1.25\,|m|\,\beta_q z\right) \exp 0.375\,|m|\,\beta_q z$$
$$\exp -3j\beta_e z\left(1-\frac{a'\omega_q}{\omega}\right). \qquad (9)$$

It can be concluded that the upper sideband is heavily excited in the beam. The growth constant is one half that obtained by Louisell and Quate;[1] therefore, the theoretical gain will be much lower than theirs and hence closer to the experimental value. The next refinement in the analysis would be the inclusion of the sidebands around the second harmonic of the pump. It is expected that this will provide still better agreement between theory and experiment, since the growth rate will be further reduced.

WWV Standard Frequency Transmissions*

The frequencies of the National Bureau of Standards radio stations WWV and WWVH are kept in agreement with respect to each other and have been maintained as constant as possible with respect to an improved United States Frequency Standard (USFS) since December 1, 1957.

The nominal broadcast frequencies should, for the purpose of highly accurate scientific measurements, or of establishing high uniformity among frequencies, or for removing unavoidable variations in the broadcast frequencies, be corrected to the value of the USFS, as indicated in the table below.

The characteristics of the USFS, and its relation to time scales such as ET and UT2, have been described in a previous issue,[1] to which the reader is referred for a complete discussion.

The WWV and WWVH time signals are also kept in agreement with each other. In addition, they are locked to the nominal frequency of the transmissions and consequently may depart continuously from UT2. Corrections are determined and published by the U. S. Naval Observatory. The broadcast signals are maintained in close agreement with UT2 by properly offsetting the broadcast frequency from the USFS at the beginning of each year when necessary. This new system was begun on January 1, 1960. The last time adjustment was a retardation adjustment of 0.02 seconds on December 16, 1959.

Tunnel Diode as an Interstage Gain Device*

The purpose of this letter is to demonstrate the applicability of the tunnel diode as an interstage coupling element with gain. It can be used in a transistor amplifier consisting of a cascade of "common-base" stages to provide impedance transformation and power gain between each stage. Fig. 1 illustrates the configuration used to obtain this impedance transformation and power gain. The gain equations are as follows:

---

* Received by the IRE, December 17, 1959.

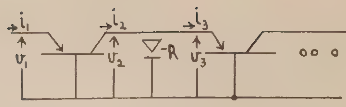

Fig. 1—Circuit configuration for tunnel diode interstage coupling, where $u_2=u_3$, and for $\infty_6=1$, $i_1=i_2$ (valid assumption for most transistors).

$$G_T=\frac{P_2}{P_1}=\frac{v_2i_2}{v_1i_1}=\frac{(-R)}{R_{\text{in}}+(-R)}$$

$$G_D=\frac{P_3}{P_2}=\frac{v_3i_3}{v_2i_2}=\frac{(-R)}{R_{\text{in}}+(-R)}$$

$$G_S=\frac{P_3}{P_1}=\frac{v_3i_3}{v_1i_1}=G_TG_D=\left[\frac{(-R)}{R_{\text{in}}+(-R)}\right]^2$$

$$\text{for stable gain } |R_{\text{in}}| < |-R|$$

$(-R)$ = negative resistance of tunnel diode
R_{in} = input resistance of common base transistor
G_t = transistor power gain
G_d = power gain per diode (interstage gain)
G_s = power gain per stage.

Since presently available diodes have negative resistance values of -40 to -200 ohms and since R_{in} for typical transistors can be controlled in this range, it is fairly simple to obtain the gain and stability desired.

A three stage IF amplifier using this coupling technique was designed and breadboarded. An over-all gain of 60 db was obtained for a bandwidth of 300 kc centered at 10 mc. The gain per transistor and the gain per diode were equal to 10 db each. Experimental tunnel (Esaki) diodes from the Sony Company in Japan were used; these had a negative conductance of -0.02 mho and a shunt capacitance of 500 $\mu\mu$f when operated in the tunnel region. The large value of shunt capacitance (500 $\mu\mu$f) was the limiting factor in the determination of center frequency and bandwidth for the desired gain. However, tunnel diodes are now being manufactured which have shunt capacitances of 15 $\mu\mu$f with the expectation that this will be reduced further in the future.

Recent Developments in Very Broad-band End-Fire Arrays*

The transmission line excited Yagi or "straight ladder" antenna, shown in Fig. 1, was developed at this laboratory in the spring of 1958. This antenna may be described as a conventional Yagi array in which the driving element has been replaced by a shunted passive element and the array excited by electromagnetic coupling to a twin-wire transmission line, the twin-wire line being developed from a coaxial line in the manner shown in Fig. 1. In Fig. 2 we show a sketch of an experimental model of a two-bay straight ladder. This antenna was ultimately built full scale for operation at VHF (Fig. 3). It had a 20-foot boom length, 50-ohm input impedance, and a minimum over-all gain of 10 db (above isotropic) in a bandwidth of ±10 per cent.

Fig. 1—Sketch of a straight ladder antenna.

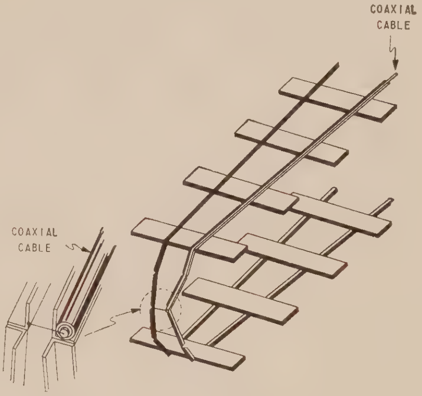

Fig. 2—Two-bay straight ladder antenna.

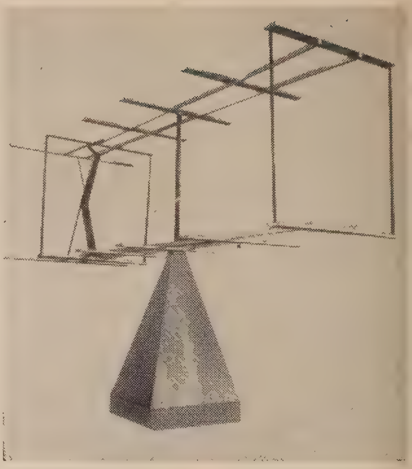

Fig. 3—Photograph of a two-bay VHF straight ladder antenna.

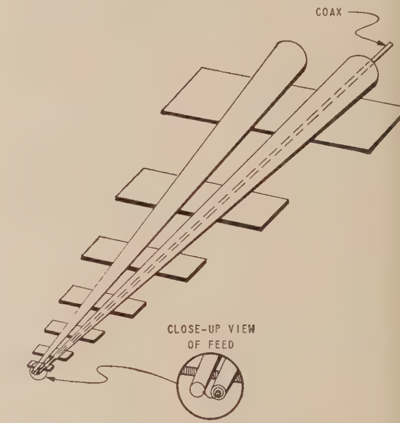

Fig. 4—Sketch of an early working model of a tapered ladder antenna.

It was subsequently realized that the ladder could be made indefinitely broad in bandwidth by using the principle employed by DuHamel and Isbell,[1] *i.e.*, by scaling the radiating elements in constant ratio. A sketch of one of our first working models of this antenna, called the "Tapered Ladder," is shown in Fig. 4. As in its predecessor, the straight ladder, the elements were electromagnetically coupled, *i.e.*, there were no conducting connections between the twin-line and the elements.

Typical *E*- and *H*-plane radiation patterns of a Tapered Ladder are shown in Fig. 5. These patterns were maintained over a bandwidth exceeding 4:1. The bandwidth can be increased simply by adding more elements. The antenna was excited from 50-ohm coaxial line, had a maximum VSWR of 2:1, and a measured gain of 8 db above isotropic.

In a later version of the Tapered Ladder we were able to match the antenna to 50 ohms with an average VSWR of 1.45:1 over a 7:1 frequency range. This was achieved by providing additional distributed loading for the twin-conductor transmission line. We have also built models with higher directivities, increase in directivity being derived from a reduction of the taper angle of the array. The taper angle is that angle subtended at the antenna vertex by each radiating element; thus, reduction of the taper angle amounts to reduction of percentage change in length of successive elements.

Other types of end-fire antennas can be made very broadband by tapering and exciting from twin-line, in particular the "Helix" and Cumming's "Zig-Zag."[2] A broadband "Tapered Zig-Zag" was developed by J. McDowell and the author. A sketch of such an antenna is shown in Fig. 6 and typical radiation patterns are shown in Fig. 7. The radiating structure of a Tapered Zig-Zag can be a slightly modified form of one-half of the V-shaped undirectional pseudo-infinite, logarithmically periodic

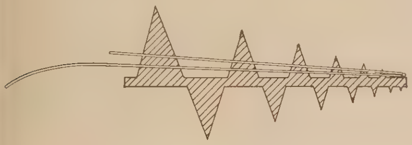

Fig. 6 Broadband tapered zig-zag.

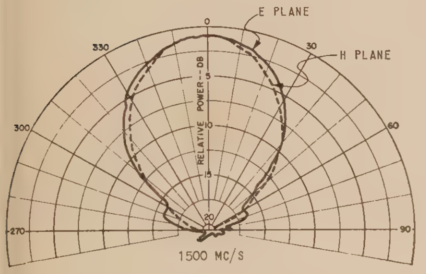

Fig. 7—Broadband tapered zig-zag radiation patterns, *E*- and *H*-planes at 1500 mc.

(PILP) antenna developed by Isbell.[3] In such case it is remarkable to note that the zig-zag structure has the same directivity as the original PILP.

We have found that the Tapered Ladder and the symmetrically excited Tapered Zig-Zag can be cut in half longitudinally and excited over a ground plane. Further, if the radiating elements are rotated 90° about their own longitudinal axes we have a transmutation to the broadband "Loaded Unipole" independently developed by Lamberty[4] at this laboratory.

The author and co-workers have made near-field amplitude measurements of the Tapered Ladder, and Franks and Bell[5] have made near-field phase and amplitude measurements of a PILP structure. In both cases we find that at any given frequency the antennas derive their directivity from an excitation length only half that of an equivalent Hansen-Woodyard array. Further, Franks and Bell find that the excess phase shift along the boom exceeds the 180° Hansen-Woodyard condition, the measured value being greater than 250°.

If we regard PILP structures, ladders, apex-fed helices[6] and spirals, line-fed zig-zags, etc. as loaded transmission lines, all of them appear to be generically related and resemble the "Comb" and "Fishbone" antennas developed several decades ago. With an analysis based on the loaded transmission line point of view, we have had fair success in predicting the radiation patterns of the Tapered Ladder. Relationships between excitation length, bandwidth, and directivity have been deduced from the uncertainty principle.

Nonreciprocal Radar Antennas*

We herewith report a successful extrapolation of the Dolph-Tchebycheff antenna concept with application to radar antennas or to any situation in which the system antenna pattern is the product of a transmitting antenna pattern and the pattern of a dimensionally-equivalent receiving antenna.

We begin by pointing out the inadequacy of the simple Dolph-Tchebycheff design in the radar case. In this design, the array factor for $(n+1)$ elements is forced by appropriate choice of feeding coefficients into a correspondence with T_n, where T_n denotes the Tchebycheff polynomial of degree n. Dolph[1] pointed out that the Tchebycheff correspondence produces the minimum beam angle for a given minor-lobe level. However, for the radar case in which the same antenna, or identical antennas, are used for transmission and reception, the system pattern (pattern and array factor are taken as equal) is $(T_n)^2$. $(T_n)^2$ is a polynomial of degree $2n$ but it is *not* equal to the Tchebycheff polynomial of the same degree (T_{2n}) and therefore the system pattern does *not* represent the optimum relationship between beam angle and minor-lobe level.

It is, however, quite simple to produce a system pattern with the desired Tchebycheff correspondence. Note first that T_{2n} is expressible in terms of T_n in the same way that the cosine of a double angle is expressible in terms of the cosine of the single angle. Thus

$$T_{2n} = 2(T_n)^2 - 1,$$

or

$$T_{2n} = 2\left(T_n - \frac{\sqrt{2}}{2}\right)\left(T_n + \frac{\sqrt{2}}{2}\right).$$

Therefore, if the excitation of the array center is adjusted to the different values between transmission and reception as implied by the above equation, the Tchebycheff correspondence for system pattern will have been realized.

This nonreciprocal action can be produced in a number of ways, perhaps the most simple of which is shown in Fig. 1. Here the power divider apportions the excitation of the array elements in accordance with $(T_n+\sqrt{2}/2)$. The isolator action is such as to leave this excitation unaltered for one direction of power flow and to introduce enough attenuation in the reverse direction to correspond to the $(T_n-\sqrt{2}/2)$ excitation.

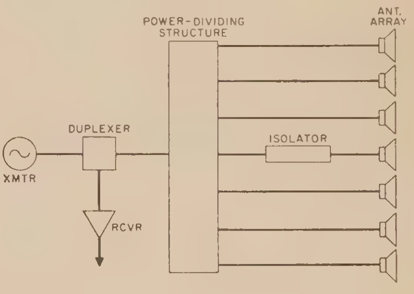

Fig. 1—Extended Tchebycheff nonreciprocal array.

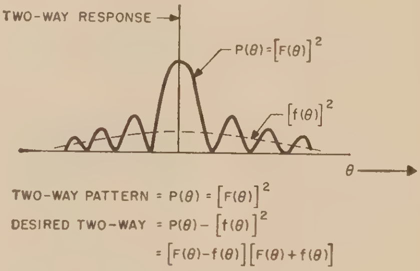

TWO-WAY RESPONSE
P(θ)=[F(θ)]²
[f(θ)]²
θ
TWO-WAY PATTERN = P(θ) = [F(θ)]²
DESIRED TWO-WAY = P(θ) − [f(θ)]²
= [F(θ)−f(θ)][F(θ)+f(θ)]

Fig. 2—Auxiliary radiator used to simultaneously sharpen beam angle and reduce sidelobes of two-way antenna pattern.

Using a given minor-lobe level as the basis of comparison, the extended Tchebycheff design will improve the beam angle by about 10 per cent over the conventional Tchebycheff design. For a given beam angle, the equivalent one-way minor-lobe improvement lies in the 4-to 5-db range.

This general principle has the simple continuous aperture analog illustrated in Fig. 2. Here the usual two-way pattern is shown as $[F(\theta)]^2$. The dotted $[f(\theta)^2]$ curve is selected to bisect exactly the largest minor lobe and may also approximately bisect several of the lesser minor lobes as well. If $[f(\theta)]^2$ could be made the angular axis (abscissa) then the minor-lobe level would be reduced by nearly 3 db and the beam angle slightly sharpened at the same time. It may be obvious by now that this effect can be produced by an auxiliary antenna whose one-way pattern is $f(\theta)$. This auxiliary antenna adds in phase to the principal lobe of the main antenna for transmission or reception, and adds in phase opposition to the principal lobe for reception or transmission. This action may be described by the algebraic relation:

$$[F(\theta)]^2 - [f(\theta)]^2 = [F(\theta) - f(\theta)][F(\theta) + f(\theta)].$$

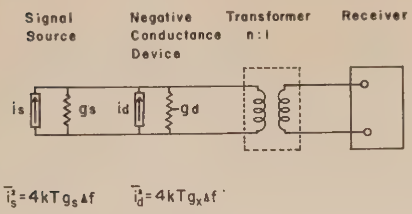
Note on the Noise Figure of Negative Conductance Amplifiers*

The problem of coupling a negative conductance amplifier stage to another stage is sometimes solved by means of a circulator.[1] The purpose of this note is to discuss two solutions that do not require the use of a circulator. One solution consists of connecting the negative conductance amplifier stage directly to a receiver; the other solution connects the stage to a receiver by means of a lossless step-down transformer of suitably chosen turn ratio n.

Let the negative conductance amplifier stage consist of a negative conductance device of conductance $-g_d$ parallel to a signal source of conductance g_s, where $g_s > g_d$. The available gain of the stage is then (see Fig. 1):

$$G_{av} = g_s/(g_s - g_d), \tag{1}$$

and the amplifier stage is stable. Let the noise of the amplifier be represented by a source current generator i_s and a device current generator i_d and let



Signal Source
Negative Conductance Device
Transformer n:1
Receiver
is
gs
id
gd
$\overline{i_s^2} = 4kTg_s\Delta f$
$\overline{i_d^2} = 4kTg_x\Delta f$

Fig. 1.

$$\overline{i_s^2} = 4kTg_s\Delta f; \quad \overline{i_d^2} = 4kTg_x\Delta f. \tag{2}$$

The noise figure F_1 of the amplifier stage, neglecting losses, is then

$$F_1 = 1 + g_x/g_s. \tag{3}$$

Let the receiver have a noise figure $F_2(g_s')$ if a signal source of conductance g_s' is connected parallel to the input, and let F_2 have the minimum value $(F_2)_{\min}$ for $g_s' = (g_s')_{\min}$. If the negative conductance amplifier stage is connected directly to the input of the receiver, the receiver looks into a source conductance $g_s' = (g_s - g_d)$; if it is connected by means of a step-down transformer, the receiver looks into a source conductance $g_s' = n^2(g_s - g_d)$, if n is the turn ratio of the transformer. In either case $g_s' > 0$, since $g_s > g_d$.

Since the output conductance $(g_s - g_d)$ of the negative conductance amplifier stage is positive, Friis' formula holds. The total noise figure F of amplifier plus receiver is

$$F = F_1 + (F_2 - 1)/G_{av}. \tag{4}$$

We first consider the case in which the negative conductance amplifier is connected directly to the receiver and we assume that $g_s' = (g_s - g_d)$ is quite small. The asymptotic value of the noise figure is then

$$F = 1 + \left[g_x + \lim_{g_s' \to 0} g_s'\{F_2(g_s') - 1\}\right]/g_s, \tag{5}$$

as is found by substituting (1). Hence, the direct connection between the stage and the receiver does not give a significant increase in noise figure if

$$\lim_{g_s' \to 0} g_s'\{F_2(g_s') - 1\} \ll g_x. \tag{5a}$$

Next, we consider the case in which a step-down transformer of turn ratio n is used to connect the stage to the receiver. The minimum noise figure $F_{\min}$ is obtained if the source conductance $g_s' = n^2(g_s - g_d)$ is adjusted so that F_2 has its minimum value. Substituting (1), we obtain for $n^2(g_s - g_d) = (g_s')_{\min}$,

$$F = F_{\min} = 1 + [g_x + (g_s - g_d) \cdot \{(F_2)_{\min} - 1\}]/g_s. \tag{6}$$

Hence, the transformer connection between the stage does not give any significant increase in noise figure if

$$(g_s - g_d)\{(F_2)_{\min} - 1\} \ll g_x. \tag{6a}$$

It is always possible to write the noise figure of the receiver as

$$F_2 = 1 + A + R_{n0}g_s' + g_{n\infty}/g_s', \tag{7}$$

where A is usually a small factor, R_{n0} is the equivalent noise resistance for short-circuited input, and $g_{n\infty}$ is the equivalent noise conductance for open-circuited input; both quantities are easily measured. The noise figure has its minimum value

$$(F_2)_{\min} = 1 + A + 2\sqrt{R_{n0}g_{n\infty}}$$

$$\text{for } g_s' = (g_s')_{\min} = \sqrt{g_{n\infty}/R_{n0}}. \tag{7a}$$

Consequently (5) may be written

$$F = 1 + (g_x + g_{n\infty})/g_s, \tag{8}$$

and (5a) becomes

$$g_{n\infty} \ll g_x. \tag{8a}$$

Eq. (6) may be written

$$F_{\min} = 1 + \{g_x + (g_s - g_d)(A + 2\sqrt{R_{n0}g_{n\infty}})\}/g_s, \tag{9}$$

and (6a) becomes

$$(g_s - g_d)(A + 2\sqrt{R_{n0}g_{n\infty}}) \ll g_x. \tag{9a}$$

The above discussion is true for any type of negative resistance amplifier such as the parametric amplifier, the tunnel diode, etc. For the tunnel diode the dc current I_d shows full shot noise[2] so that

$$\overline{i_d^2} = 2eI_d\Delta f, \text{ or } g_x = (e/2kT)I_d. \tag{10}$$

In the case of the parametric amplifier, neglecting losses, the noise figure F_1 is[3]

$$F_1 = 1 + \frac{g_{ci}}{g_s}\frac{\omega_i}{\omega_0}, \tag{11}$$

where $-g_{ci}$ is the negative input conductance caused by the idler circuit, ω_i is the input frequency, and ω_0 is the idler frequency. Consequently,

$$g_x = g_{ci}\frac{\omega_i}{\omega_0}. \tag{11a}$$

The discussion has neglected to mention losses in the circuits, in the transformer, and, in the case of the parametric amplifier, the losses in the parametric device itself. It has also ignored the possibility of cooling some of the components, *e.g.*, the parametric device and the idler circuit in parametric amplifiers. It is not difficult to extend the discussion to include these effects.

A tunnel diode has a much lower impedance level than a parametric amplifier and as a consequence (5a) and (6a) and their equivalents are much more easily satisfied for the former than for the latter. Also, the influence of circuit losses will be less pronounced.

The authors are indebted to W. F. Leverton, Raytheon Manufacturing Company, Waltham, Mass., and R. L. Watters, General Electric Research Laboratory, Schenectady, N. Y., for discussion and correspondence.

Donald L. Birx (S'49–A'51–M'54) was born in Baltimore, Md., on November 30, 1924. He received the B.E.E. degree from The Johns Hopkins University, Baltimore, Md., in 1944. In 1945, he entered the U. S. Navy and was employed as an instructor in the Radio Materiel School, Washington, D. C. In 1946, he re-entered The Johns Hopkins University in the graduate school, and received the Dr. Eng. degree in electrical engineering in 1951.

D. L. Birx

Since 1951, he has been with the Franklin Institute in Philadelphia, Pa., where he is currently a senior staff engineer in the electronics branch of the laboratories. At present, he is working in the measurements field, being concerned primarily with the measurement of low-level RF powers and the utilization of natural radiation in the navigation of space vehicles. Prior to this work, he was engaged in a variety of projects which have included the statistical design of experiments for the analysis of optical and electrical systems, the synthesis of networks utilized in the design of RF noise filters, and the study of nonlinear aspects of rate gyroscopes.

Dr. Birx is a member of the American Physical Society, Tau Beta Pi, Sigma Xi, and the Scientific Research Society of America.

⁂

Robert L. Blanchard (S'55) was born in Montreal, Can., on May 8, 1919. He received the B.S. degree in engineering physics from McGill University, Montreal, in 1941 and the M.S. degree in applied physics from Harvard University, Cambridge, Mass., in 1948.

R. L. Blanchard

In 1941 and 1942, he was appointed Instructor in physics at McGill University, and in 1953 and 1954 he served as lecturer on microwave theory and technique in the Graduate School, Evening Division, at Northeastern University Boston, Mass. He was in charge of Communication Research and Development for the Canadian Army Signal Corps in 1945 and 1946, following which he joined Raytheon Manufacturing Company, Waltham, Mass., where he developed UHF communication equipment. He was a consultant on electronic development and design for several companies in the Boston area during 1948–1949. In 1949, he joined Trans-Sonics, Inc., Burlington, Mass. where his work has comprised general applied physics with application to measurement and control, electromagnetic theory, microwave systems, network theory, and filter design. He was leader of the team that developed the first successful trajectory scoring system for ammunition and missiles directed at airborne targets. He has held senior positions at Trans-Sonics, Inc., including Chief Research Engineer 1952–1957, Chief Engineer, Electronics Division 1957–1958, and is presently Vice-President and Director of New Product Research.

⁂

Frederick E. Bond (M'47–SM'55) was born on January 10, 1920, in Philadelphia, Pa. He received the B.S.E.E. degree from Drexel Institute of Technology, Philadelphia, in 1941, the M.S.E.E. degree from Rutgers University, New Brunswick, N. J., in 1950, and the D.E.E. degree from Polytechnic Institute of Brooklyn, N. Y., in 1956.

F. E. Bond

During World War II, he served with the U. S. Army Signal Corps in Europe, where his assignments included research and development on British fire control radar for coastal artillery, and staff planning for the use of electronic countermeasures. From May, 1946, to July, 1957, he was with the Communications Department of the U. S. Army Signal Engineering Laboratories at Fort Monmouth, N. J., engaged in research and development of ground radio and wire transmission equipments and communication systems engineering. His last position there was Director of the Radio Communications Division. At present he is a member of the senior staff of the Ramo Wooldridge Division of Thompson Ramo Wooldridge Incorporated.

Dr. Bond is a member of Sigma Xi, Tau Beta Pi, and Eta Kappa Nu. He is a Lieutenant Colonel in the U. S. Army Reserve.

⁂

Milton H. Brockman (S'43–A'54–M'50–SM'53), for a photograph and biography, please see page 264 of the February, 1960 issue of PROCEEDINGS.

A. E. Brown

Alvin E. Brown (S'48 – A'49 – M'55) was born in Tacoma, Wash., on March 4, 1926. He received the B.S. E.E. degree in 1948 from the University of Washington, Seattle.

He joined the Boeing Airplane Co. in 1948 at Holloman Air Force Base, N. M., as a telemetry engineer for the duration of the GAPA Program. In 1950, he worked for Northrop as a radio control engineer on the SNARK Program. He joined Land-Air, Inc. at Holloman in 1951. He worked in the field of electronics trajectory and served on the IRIG for three years. He joined Lockheed Missiles and Space Division at Palo Alto, Calif., in 1959 in the field of instrumentation research.

◆

S. P. Brown

Samuel P. Brown (SM'59) was born on November 25, 1921, in Greensburg, Pa. He received the B.S. E.E. degree in 1942 from Pennsylvania State University, University Park, and the M.S.E.E. degree from Rutgers University, New Brunswick, N. J., in 1950. He received additional army electronics training at the General Electric Company, Schenectady, N. Y., taking courses in radio and radar techniques.

From January, 1943, to August, 1946, he was in military service, and was responsible for the system and field evaluation of newly developed microwave radio relay systems at the Signal Corps Ground Signal Agency. He is currently in the U. S. Army Reserve as a Major in the Signal Corps. His present title is Director, Astro-Electronics Division, Communications Department (supervisory electronic engineer) at the U. S. Army Signal Research and Development Laboratory, Fort Monmouth, N. J.

◆

Harry R. Buchanan (A'47–M'55) was born in Lawrence County, Ill., on March 26, 1921. He received the B.S. degree in engineering physics from the University of Illinois, Urbana, in 1943. After graduation, he entered the General Electric Company's Engineering Training Program for one year.

In 1944 he joined the Electronics Department of the General Electric Co., Schenectady, N. Y. From 1944 until 1955, he was engaged in the design and development of microwave components used in high power military and commercial radar systems. In 1955, he joined the engineering staff of the Jet Propulsion Laboratory, California Institute of Technology, Pasadena. At present, he is a member of the Electronics Research Section, engaged in microwave research activities relating to long-range space communications systems.

H. R. Buchanan

Mr. Buchanan is a member of RESA.

◆

C. R. Cahn

Charles R. Cahn (S'51–A'52–M'57) was born on October 7, 1929, in Syracuse, N. Y. He received the B. E. E. degree in 1949, the M. E. E. degree in 1951, and the Ph. D. degree in electrical engineering in 1955, all from Syracuse University, Syracuse, N. Y.

From 1949 to 1956, he served as instructor and later as assistant professor in the Electrical Engineering Department of Syracuse University, where he was engaged in research work in information theory and microwave antennas and in studies on systems engineering. From 1952 to 1953, on a leave of absence, he was employed in the System Planning Department of the Niagara Mohawk Power Corporation, Buffalo, N. Y., where he was concerned with system planning and econonic operation of a large integrated power system. At present, he is a member of the senior staff of Ramo-Woolridge, a division of Thompson Ramo Wooldridge, Inc., Los Angeles, Calif., where he is working on systems analysis and synthesis, with emphasis on applications of information theory in the field of digital communications. He has also investigated techniques for electronic countermeasures and methods of achieving reliable transmission over fluctuating circuits.

Dr. Cahn is a member of Sigma Xi and the AIEE.

◆

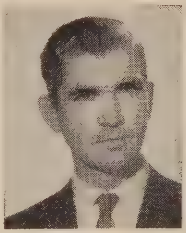
William O. Campbell (M'55) was born on August 26, 1920 in Natchez, Miss. He received the B.S.E.E. and M.S.E.E. degrees in 1948 and 1949, respectively, from the University of Tennessee, Knoxville.

From 1943 to 1946, he served with the U. S. Army Air Corps as a meteorologist. From 1949 to 1955, he was associated with Bendix-Friez in Baltimore, Md., where he was instrumental in the design of an automatic readout mercury barometer and an analog-digital computer for radiosonde data computation. Since 1955, he has been with The Martin Company, Baltimore, where, from 1955 to 1957, he was in charge of design groups for automatic checkout equipment for the Mace and Lacrosse Missiles. During 1957 and 1958, his position as staff Unit Head involved work on the Titan countdown equipment. Presently in the Space Flight Division, he is responsible for the electronic support equipment for space programs. He is currently enrolled in the graduate curriculum of Engineering Management at Drexel Institute of Technology, Philadelphia, Pa.

W. O. Campbell

Mr. Campbell is currently serving on the Test Equipment Committee of the Electronic Industries Association. He has recently filed a patent disclosure for digital checkout equipment.

◆



R. L. Choate

Robert L. Choate (S'50–A'52–M'57) was born on November 30, 1918, in Reevesville, Ill. He attended the University of Missouri School of Mines and Metallurgy, Rolla, where he received the B.S.E.E. degree in 1950 and the M.S. degree in physics in 1951.

From 1951 to 1953, he was employed by Bell Aircraft Corporation as electronics engineer in the development of missile guidance systems. In 1953, he returned to the Missouri School of Mines, where he served as instructor in physics and engaged in graduate studies in mathematics, physics, and electrical engineering. He has been employed at the Jet Propulsion Laboratory, California Institute of Technology, Pasadena, since 1955 as systems analyst in the Electronics Research Section. There he has been concerned with communication systems analysis, noise and filter theory, phase-locked-loop theory, secure communications, and deep space communications and tracking. He has participated in the Explorer series of satellite experiments and the lunar probe experiments (Pioneer III and IV).

Mr. Choate is a member of Sigma Xi and Sigma Pi Sigma.

◆

G. M. Clemence was born in Greenville, R. I., on August 16, 1908. He received the Ph.B. degree from Brown University, Providence, R. I., in 1930. He also received an Honorary D.Sc. degree from Case Institute of Technology, Cleveland, Ohio, in 1954.

He has been an astronomer at the U. S. Naval Observatory, Washington, D. C. since 1930. From 1945 to 1958, he was Director of the Nautical Almanac, and since 1958 he has been Scientific Director. He was a visiting professor of astronomy at Columbia University, New York, N. Y., in 1958, and has also written articles on positional astronomy, celestial mechanics time measurement, astronomical constants, mathematical tables, and navigation.

G. M. Clemence

Dr. Clemence is a member of the Senior Scientists Council of the Navy Department, the National Academy of Sciences, the American Academy of Arts and Sciences, the American Astronomical Society, the Bureau des Longitudes (France), the International Astronomical Union (of which he was President of the Commission on Celestial Mechanics from 1948 to 1955), and a foreign associate of the Royal Astronomical Society (England).

◆

R. T. Craig

Robert T. Craig was born on October 10, 1927, in Niagara Falls, N. Y. He received the B.S.E.E. degree from Massachusetts Institute of Technology, Cambridge, and the M.S.E.E. degree from Case Institute of Technology, Cleveland, Ohio. As a project engineer with the National Advisory Committee for Aeronautics from 1949 to 1955, he worked on the design and installation of controls and instrumentation for propulsion test facilities. He conducted research on control systems for gas turbine engines and wrote several NACA reports on gas turbine engine dynamic characteristics, control systems, and computer techniques.

He joined Thompson Ramo Wooldridge Inc., Cleveland, Ohio, in 1955 and directed design and development in advanced propulsion control systems and large-scale simulation studies. He has conducted system optimization and control analyses of nuclear power system and pneumatic controls, and has directed design of new analog computer components. He has directed trajectory and propulsion system analysis of electrically propelled vehicles, and has conducted research in high-temperature materials in the field of ion propulsion. He is now in charge of projects in propulsion system optimization, and experimental ion and plasma physics programs at the New Devices Laboratories, Thompson Ramo Wooldridge, Inc.

Mr. Craig is a member of AIEE, ARS, and Sigma Xi.

◆

W. Reed Crone (S'52–M'55) was born in Albert City, Iowa, on January 25, 1931. He attended the Milwaukee School of Engineering, Milwaukee, Wis., from 1948 to 1950, after which he served in the U. S. Navy as an electronic technician. In 1952, he was discharged to participate in the NROTC program at the University of Wisconsin, Madison, and received the B.S.E.E. and Bachelor of Naval Science degrees from that institution in 1955. He then re-entered the naval service and was assigned as Electrical Officer on an aircraft carrier until his release in 1958. Since that time, he has been pursuing graduate studies in electrical engineering and acting as research assistant at The Ohio State University Radio Observatory, Columbus, Ohio.

W. R. Crone

Mr. Crone is a member of Eta Kappa Nu and Tau Beta Pi and an associate member of the AIEE.

◆

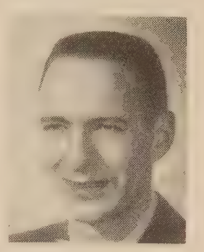
A. F. Daniel

Arthur F. Daniel was born in Birmingham, Ala., on September 27, 1905. He received the B.S. degree in chemistry in 1927 and the M.S. degree in physics in 1928, both from the University of North Carolina, Chapel Hill. From 1928 to 1929 he attended the University of Chicago, Chicago, Ill., on a Charles A. Coffin fellowship in physics.

From 1929 to 1932, he was a research associate in electrical engineering at Harvard University, Cambridge, Mass. From 1933 to 1935, he was a research physicist with the General Chemical Co., Long Island, N. Y., and from 1935–1941, he was also a research chemist with the Storage Battery Division of T. A. Edison, Inc., West Orange, N. J. From 1941–1956, he was chemical engineer and Chief of the Battery Development Section of the U. S. Army Signal Research and Development Laboratory, Fort Monmouth, N. J. Presently he is a USASRDL general engineer and director of the Power Sources Division, Electronic Components Research Department, Fort Monmouth, where he is responsible for direction and coordination of research and design and development program to provide energy sources and energy conversion devices for use with U. S. Army Signal Corps equipment. In the field of primary batteries and special-purpose batteries, he is responsible for directing a research and development program for the Army and Air Force, and has received an Army exceptional civilian service award for battery research and development.

Mr. Daniel is a member of the American Chemical Society, the Electrochemical Society, the American Physical Society, the Armed Forces Communication Association, the Armed Forces Management Association, Sigma Xi, and Sigma Phi Sigma. He is listed in "American Men of Science."

◆

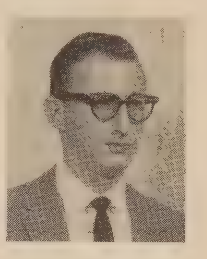


J. B. Day

John B. Day was born on March 3, 1928 in Erie, N. D. He served with the U. S. Navy as an airborne electronics technician from 1946 to 1951. In 1954, he received the B.A. degree in mathematics from San Jose State College, San Jose, Calif., and has studied graduate mathematics there and at Purdue University, Lafayette, Ind. After three years spent in teaching secondary mathematics in California and Indiana, he joined the Philco Western Development Laboratories, Palo Alto, Calif., in June, 1959. He is presently an engineer in the advanced applications section there.

Mr. Day is a member of Tau Delta Phi and Kappa Delta Pi.

◆



R. H. Dimond

Robert H. Dimond was born in Madison, Wis., on March 6, 1931. He received the, B.S.E.E. degree in 1955 from the Milwaukee School of Engineering, Milwaukee, Wis.

He joined Radiation, Inc., Orlando, Fla., in 1956 as an engineer in the Instrumentation Division. His work there has included contributions in atomic effects and complete environmental testing of airborne electronic systems; FM/FM, PPM/AM, PCM/FM telemetry systems; oscillographs; tape recorders; and associated instrumentation. He is currently with the Research Division of Radiation, Inc., which he joined in 1958 as a senior staff engineer. Included in his work there have been military technical intelligence evaluations and systems engineering in radio telemetry.

◆

E. F. Dirsa

Edward F. Dirsa (M'56) was born in Brighton, Mass. on October 20, 1925. He received the B.S. degree in physics from Boston College, Chestnut Hill, Mass. in 1950, and the M.S. degree in physics from Indiana University, Bloomington, in 1952.

From 1952 to 1954, he was engaged in magnetron tube development with Sylvania Electric Products, Inc., Boston, Mass. From 1954 to 1958, he was associated with Cook Research Laboratories, Morton Grove, Ill, where he worked on studies of electromagnetic propagation, design and analysis of countermeasures equipment and radar systems, and design of a unique radar target range for the Air Force. He is presently engaged in military systems engineering with the Admiral Corporation, Chicago, Ill.

◆

R. L. EASTON

Roger L. Easton (M'46) was born in Craftsbury, Vt., on April 30, 1921, and received the B.A. degree in physics from Middlebury College, Vt., in 1943.

Since that time he has been at the U. S. Naval Research Laboratory, Washington, D. C. He has worked on radar beacons, IFF, and on rocket and satellite tracking equipment. He worked on the design of the Minitrack system and had design responsibility for the 1958 Beta 2 (Vanguard I) satellite. He is now responsible for the detection portion of the Navy's dark satellite tracking program as head of the Space Surveillance Branch, NRL.

Mr. Easton is a member of the ARS.

◆

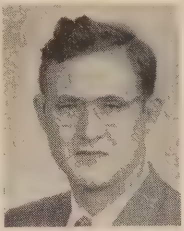
D. H. ELLIS

Donald H. Ellis (M'59) was born in Spartanburg, S. C., on March 8, 1927. He received the B.E.E. degree from Clemson College, Clemson, S. C., in 1951.

From 1944 to 1948 he served with the U. S. Navy. After graduating from college, he worked from 1951 to 1954 with the Atomic Energy Division of the E.I. du Pont deNemours Company on the control instrumentation of nuclear reactors. He then spent four years at the Massachusetts Institute of Technology's Lincoln Laboratory, Lexington, Mass., on the design and development of magnetic-core memory for digital computers. His prime responsibility was the development of a 256×256 coincident current magnetic-core memory for use in a large-scale digital computer, but he was also associated with the development of a high-speed transistorized core memory for use in a solid-state digital computer. At present, he is the Systems Development Unit Head involved in the design and development of airborne PCM data acquisition systems at Radiation, Inc., Melbourne, Fla.

Mr. Ellis is a member of Tau Beta Pi.

◆



C. W. FETHEROFF

Charles W. Fetheroff was born on April 9, 1930, in East Cleveland, Ohio. He received the B.S.E.E. degree from Case Institute of Technology, Cleveland, Ohio, and has taken advanced work in servomechanisms, mathematics, circuit analysis, electronic circuits, electromagnetic theory, and atomic physics. He served in the U. S. Army Signal Corps from 1953 to 1955, doing research and development work on integrated radar defense systems.

Since joining Thompson Ramo Wooldridge, Cleveland, Ohio, in 1952, he has been responsible for electronic and magnetic component design, system stability studies for parallel alternators, design and development of auxiliary power unit simulators, and parametric analysis and startup stability studies on the Tartar and Terrier APU speed controls. He has performed hot gas servo analyses and has done research and development on electronic and mechanical components for application in extremely high ambient temperatures. In the field of advanced space propulsion, he has performed analysis and comparison of capabilities of chemical and electric propulsion systems, and is now in charge of refined studies on performance comparison of these two systems.

Mr. Fetheroff is a member of AIEE, ARS, Tau Beta Pi, Sigma Xi, and Eta Kappa Nu.

◆

J. J. FLEMING

James J. Fleming (A'42–M'55) was born in Chicago, Ill., on February 26, 1917. He received the B.S. degree in physics at Northwestern University, Evanston, Ill., in 1938. In 1941, after three years of graduate study in physics and service as a research assistant at Northwestern, he joined the Radio Division of the U. S. Naval Research Laboratory, Washington, D. C. During World War II, he contributed to the development of plan position indication for search radars. He was also responsible for the operational evaluation of Navy anti-aircraft gun fire-control systems, for which he received the Meritorious Civilian Service Award.

Since 1945, he has been Head of the Operational Research Branch at the U. S. Naval Research Laboratory, first in Radio Division III and now in the Applications Research Division. In addition to the development of the NRL Electronic Digital Computer (NAREC), the program of the Branch has included, for Project Vanguard, the development of an automatic telemetered data reduction facility (ARRF), a radar-computer ground-controlled third-stage firing system, and the Vanguard Computing Center. Currently, the Branch is engaged in the data processing problem of the Space Surveillance program.

Mr. Fleming is a member of the American Physical Society, the Association for Computing Machinery, the Scientific Research Society of America, and Phi Beta Kappa.

◆

R. FRANKLIN

Rachel Franklin was born in Dudley, N. J., on March 27, 1897. She received the B.A. degree from Vassar College, Poughkeepsie, N. Y., in 1919, and the M.A. degree from the University of Pennsylvania, Philadelphia, in 1929.

Her main interests have been in the field of optics and in the design of optical instruments. From 1930 to 1942, she was associated with the Biochemical Research Foundation in Newark, Del., working on the effects of ultraviolet radiation on living tissues and protozoa, and on the absorption spectra of normal and cancerous tissues. During World War II, she was employed by the U. S. Army Signal Corps, Ft. Monmouth, N. J., as an engineer in the development and inspection branch. In 1946, she joined the staff of the Franklin Institute Laboratories, Philadelphia, Pa., as a research physicist. She has worked in that capacity on various projects involving optics, including ultraviolet and infrared absorption spectroscopic studies and the design of specialized instruments for this work.

Miss Franklin is a member of the Optical Society of America, Phi Beta Kappa, and the Scientific Research Society of America, Franklin Institute Branch.

◆

W. H. GUIER

William H. Guier was born on July 13, 1926, in Wichita, Kans. He received the B.S. degree in 1948, the M.S. degree in 1950 and the Ph.D. degree in theoretical physics in 1951, all from Northwestern University, Evanston, Ill.

He joined the Applied Physics Laboratory of The Johns Hopkins University, Silver Spring, Md., in 1951, and is now a principal staff member in the field of theoretical physics. He recently received the "Outstanding Young Scientist" award which is sponsored by the Maryland Academy of Science.

Dr. Guier is a member of Lambda Chi Alpha, the American Physical Society, and the Philosophical Society of Washington, D. C.

◆

William R. Haseltine was born in Chicago, Ill., on June 27, 1911. He received the B.S. and Ph.D. degrees in physics in 1934 and 1938, respectively, from the Massachusetts Institute of Technology, Cambridge, Mass. He was a teaching fellow at M.I.T. in 1935 and 1936, an assistant in mathematics at the University of Wisconsin, Madison, in 1936 and 1937, and a research fellow in physics and lecturer at the University of California, Berkeley, from 1938 to 1941. From 1941 to 1945, he was an officer in the U. S. Army Ordnance Department.

W. R. Haseltine

Since 1946, he has been a physicist, primarily in rocket ballistics, at the U. S. Naval Ordnance Test Station, China Lake, Calif.

◆

Robert C. Higgy (A'26–SM'45) was born in Columbus, Ohio, on December 7, 1901. He received the B.S.E.E. degree from The Ohio State University, Columbus, in 1925 and the Professional Electrical Engineering degree in 1937.

R. C. Higgy

Since 1925, he has been employed by The Ohio State University as Director of Broadcasting Stations, Associate Professor of Electrical Engineering, and since 1956 as Associate Director for Engineering for radio and television stations and Assistant Director of the Radio Observatory. Recently, his work has included teaching electrical engineering and research work related to ionization effects due to earth satellites. He is the author of a book on fundamental radio experiments and of articles on ground wave propagation.

Mr. Higgy is a member of Sigma Xi and a licensed Professional Engineer in Ohio.

◆

Donald C. Hock was born in North Tonawanda, N. Y., on April 18, 1929. He received the B.A. degree from the University of Buffalo, N. Y., in 1951, the M.S. degree from the A & M College of Texas, College Station, in 1952, and the Ph.D. degree in physics from Pennsylvania State University, University Park, in 1956.

D. C. Hock

He joined the Applied Physics Laboratory of The Johns Hopkins University, Baltimore, Md., in 1955 as a member of the Senior Staff, and since 1958, has been with the Research Division of Radiation Incorporated, Orlando, Fla.

Dr. Hock is a member of Sigma Pi Sigma, Phi Kappa Phi, Pi Mu Epsilon, and Sigma Xi.

Conrad H. Hoeppner (SM'47–F'58) was born on March 12, 1918, in Spooner, Wis. He received the B.S.E.E. degree in 1939 and the M.S.E.E. degree in 1940, both from the University of Wisconsin, Madison. He did graduate work at the Massachusetts Institute of Technology, Cambridge, and received the professional E.E. degree in 1947 from the University of Wisconsin.

C. H. Hoeppner

Thereafter, he was employed by the U. S. Naval Research Laboratories, Washington, D. C.; he was Director of the Electronics Laboratory, Glenn L. Martin, Co., Baltimore, Md.; Director of the Engineering Products Department, Raytheon Manufacturing Company, Waltham, Mass.; Vice President and Director of General Electronics Laboratory, Inc., Cambridge, Mass.; Manager of the Electronic Division, W. L. Maxson Corp., New York, N. Y.; and Manager of the Development Division, Stavid Engineering, Plainfield, N. J. He is presently Chief Scientist at Radiation, Inc., Melbourne, Fla.

Mr. Hoeppner is a member of Sigma Xi, Pi Mu Epsilon, Phi Kappa Phi, Phi Eta Sigma, Tau Beta Pi, and Eta Kappa Nu, and is a Fellow of Tau Beta Pi, and the Wisconsin Alumni Research Institute.

◆

Hyman Hurvitz (M'53) was born in Boston, Mass., on February 18, 1910. He received the B.E.E. degree from Northeastern University, Boston, in 1930, and the L.L.B. and M.P.L. (Master of Patent Law) degrees from Washington College of Law (now American University), Washington, D. C., in 1936 and 1937, respectively.

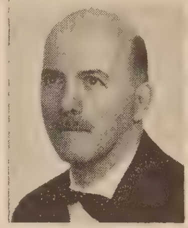
H. Hurvitz

He became a member of the Washington, D. C. Bar in 1937, and from 1942 to 1945, he served in the U. S. Navy, rising to the position of Lieutenant Commander. Since that time he has been in private practice, presently with the firm of Hurvitz and Rose, Washington, D. C.

◆

H. P. Hutchinson (A'32–SM'46) was born in Brooklyn, N. Y., in 1908. He received the B.S.E.E. degree from the Polytechnic Institute of Brooklyn, Brooklyn, N. Y., in 1930 and the M.S.E.E. degree from Columbia University, New York, N. Y., in 1933.

He has held numerous scientific and engineering positions, the most recent being Research Engineering, National Bureau of Standards; Chief Engineering, U. S. Army Aviation Center; and Assistant Director of Research, U. S. Army Signal Research and Development Laboratory, Ft. Monmouth, N. J. During World War II and in the Korean emergency, he served on military duty at the Pentagon directing Signal Corps' participation in nuclear weapons tests and in applied research.



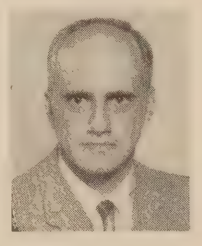
H. P. Hutchinson

Commencing with the first Sputnik, he has been continuously engaged in research on satellite signals and, together with P. R. Arendt, has written several papers on satellite radio propagation, His present position is Special Assistant to the Chief, Applied Physics Division, U. S. Army Signal Research and Development Laboratory.

Mr. Hutchinson is an Associate Member of Commission 3, USA National Committee of URSI.

◆

Donald J. Jacoby (M'46) was born in New York, N. Y., on July 8, 1920. He received the B.S.E.E. degree from Columbia University, New York, in 1941, and the M.S.E.E. degree from Rutgers University, New Brunswick, N. J., in 1950.



D. L. Jacoby

Since 1941, he has been employed at the U. S. Army Signal Research and Development Laboratory, Fort Monmouth, N. J., with the exception of three years as a radar officer in the U. S. Navy. He has been engaged in research and development programs in fields of multiplexing, radio relay and tropospheric scatter, and until recently was chief of the Radio Relay Branch of the Transmission Facilities Division. He is currently deputy director of the Astro-Electronics Division, USASRDL, with responsibility for directing programs in satellite communications, satellite instrumentation and tracking. He holds a patent on "Pulse Code Modulation."

◆

James R. Jenness, Jr. was born in Atlanta, Ga., on February 5, 1925. He received the B.S. degree in physics and mathematics from Parsons College, Fairfield, Iowa, in 1945 and the M.A. degree in physics from Temple University, Philadelphia, Pa., in 1954.

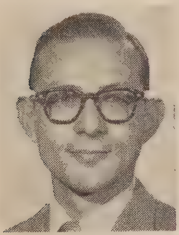
J. R. Jenness, Jr.

In 1945–1946, he taught mathematics in the high school at Birmingham, Iowa, was appointed to a graduate assistantship in physics at the

State University of Iowa, Iowa City, in 1946–1947, and in 1947–1948, was a senior fellow in physics at Iowa State College, Ames. From 1948 to 1951, he worked on special instrument calibration problems and the development of aeronautical research instruments for the NACA at Langley Field, Va. From 1951 to 1956, he was a physicist at the U. S. Naval Air Development Center, Johnsville, Pa., where his field of interest was infrared optics and guidance systems. Since 1956 he has been a Senior Physicist at HRB-Singer, Inc., State College, Pa., where he introduced the Hass-Erbe-Bradford replica mirror process for adaptation to large-scale production of low-cost precision reflective optical components by the Singer Military Products Division, and also developed techniques for fabricating paraboloidal microwave antennas by centrifugal casting. He has had a continuing interest in research instrumentation and the functioning of instruments and electronic components under unusual environmental conditions.

Mr. Jenness is a member of Phi Kappa Phi, Sigma Pi Sigma, Chi Beta Phi, the Optical Society of America, and the Association for Applied Solar Energy.

⁂



C. S. Josias

Conrad S. Josias (S'50,–A'51,–M'56) was born in New York, N. Y., on June 12, 1930. He received the B.E.E. degree from New York University, New York, in 1951 and the M.E.E. degree from the Polytechnic Institute of Brooklyn, N. Y., in 1955.

He was employed by Airborne Instruments Laboratory, Mineola, N. Y., from 1951 to 1956, during which time he was active in the development of electronic devices and systems. In 1956, he joined the Jet Propulsion Laboratory, California Institute of Technology, Pasadena, where he participated in the development of transistor circuits for missile guidance systems and space payload instrumentation. At present, he is a senior research engineer in the JPL Space Instruments Section.

⁂

S. W. Kash

Sidney W. Kash was born on March 1, 1922, in New York City, N. Y. He received the Ph.D. degree in physics in 1951, from the University of California at Los Angeles.

During World War II, he worked at the Naval Ordnance Laboratory in Washington, D. C., on underwater degaussing problems. In 1947, he participated in a spectroscopic program related to the V2 firings at White Sands, N. M. In the early part of 1951, he designed equipment for the automatic measurement of skylight polarization for the Meteorology Department at UCLA. For the next four years, he was a senior engineer at Atomics International in Canoga Park, Calif., engaged in research and development of thermal neutron reactors. He has been with Lockheed Aircraft Corporation, Palo Alto., Calif., since the latter part of 1955, and is presently manager of the Ionic Physics Department. While at Lockheed, he has been engaged in a number of activities, including the design of high-pressure and electromagnetic shock tubes and research in plasma physics, hydromagnetics, and electrical propulsion.

⁂

P. E. Kendall

P. E. Kendall (SM'56) was born in Paoli, Ind., on July 27, 1921. He received the B.S.E.E., M.S.E.E. and Ph.D. degrees from Purdue University, Lafayette, Ind., in 1948, 1949 and 1953, respectively.

He has taught undergraduate courses in electrical engineering at Purdue, and is an affiliate assistant professor at that university, teaching graduate courses in automatic controls and pulse circuitry. At ITT Laboratories, Fort Wayne, Ind., he has worked on system analysis and design of missile and space vehicle guidance and navigation systems; research in the field of nonlinear mechanics as applied to servomechanisms; optimization of contactor servos, and mercury drop noise generators in microwave frequencies; analysis of space vehicle trajectories; development of navigational equipments including Loran and radar altimeters; and operation and maintenance of military communications and radar equipments. He has held administrative positions as Head of the Electromechanical Section of the Advanced Development Department, Head of the Systems Analysis and Design Section of the Astrionics Laboratory, the position which he now holds.

Dr. Kendall is a member of Eta Kappa Nu and Sigma Xi. He has two patents pending.

⁂

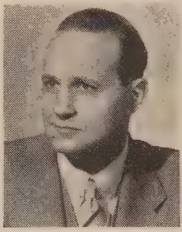
R. L. Kent

Robert L. Kent (M'59) was born in Philadelphia, Pa., on May 25, 1929. He attended the Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, where he received the B.S. degree in 1950, and the Massachusetts Institute of Technology, Cambridge, Mass., where he received the M.S. degree in 1952.

From 1950 to 1952, he was a research assistant in electrical engineering at M.I.T. Since that time, he has been a staff member of the Research Laboratory of Electronics, M.I.T., participating in the development of missile guidance and electronically scanned radar systems.

Mr. Kent is a member of Eta Kappa Nu, Sigma Tau, and Tau Beta Pi, and an associate of Sigma Xi.

⁂



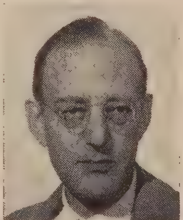
J. D. Kraus

John D. Kraus (A'32–M'43–SM'43–F'54) was born in Ann Arbor, Mich., on June 28, 1910. He received the B.S. degree in 1930, the M.S. degree in 1931, and the Ph.D. degree in 1933, all from the University of Michigan, Ann Arbor.

From 1934 to 1935, he did research on industrial noise-reduction problems and from 1936 to 1937, was engaged in nuclear research with the newly completed University of Michigan cyclotron. From 1938 to 1940, he was an antenna consultant. In 1940, he joined the Naval Ordnance Laboratory, Washington, D. C., working on the degaussing of ships, and in 1943, he became a member of the Radio Research Laboratory at Harvard University, Cambridge, Mass. In 1946, he joined the faculty of The Ohio State University, Columbus, where he is now professor of electrical engineering, professor of physics and astronomy, and Director of the Radio Observatory. He is responsible for the development of the helical beam antenna, the corner-reflector antenna, and other antenna types.

Dr. Kraus is a member of the American Astronomical Society and the American Physical Society.

⁂

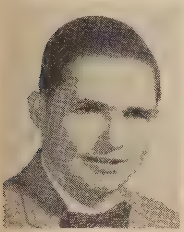


L. R. Malling

Leonard R. Malling (A'31–VA'39–M'59) was born in London, Eng., on July 9, 1909. He graduated from Northampton Technical Institute, London, Eng., in 1931 and came to this country in 1938.

For some 30 years, he has done research and design engineering in such areas as radar, nuclear resonance, aircraft guidance, guided missiles, and space vehicles. During this time, he has been employed by Hazeltine Electronics Corporation, Boeing Airplane Company, Convair, Varian Associates, and the U. S. Naval Laboratory, San Diego, Calif. In 1955 he joined the staff of the Jet Propulsion Laboratory, California Institute of Technology, Pasadena, where he is presently a senior research engineer.

◆



F. N. McMillan

F. N. McMillan was born on May 26, 1923, in Fayetteville, N. C. He received the B.S. degree with a group major in chemistry, mathematics and German from the University of Florida, Gainesville, in 1947 and the M.S. degree in chemistry from the same school in 1949.

From 1950 to 1955, he served as a chemist in the Florida Food and Drug Laboratory in Tallahassee. While in Tallahassee, he did additional graduate work in chemistry at Florida State University. From 1955 to 1958, he served as a research chemist at Eglin Air Force Base, Fla. Since 1958, he has been with the Research Division of Radiation Incorporated, Orlando, Fla. His work has included chemical kinetics, spectroscopy, immunology, organic synthesis, incendiaries, instrumentation, re-entry, and rocket propulsion.

Mr. McMillan is a member of Sigma Xi and the American Chemical Society.

◆

H. F. Meyer

Harold F. Meyer (SM'50) was born in New York, N. Y., on September 2, 1916. He attended Boston University, Boston, Mass., and Columbia University, New York, N. Y.

For many years he was active as a radio experimenter, amateur, member of the Naval Communication Reserve, and in the radio business. Entering Government service in the Signal Corps Plant Engineering agency in 1942, he became Chairman and Technical Secretary of the Technical Coordination Committee and Chief of the Engineering Coordination Section. In 1945, he transferred to the U. S. Army Research and Development Laboratories, Ft. Monmouth, N. J., and became Chief Engineer of the Long-Range Equipment Section. In 1955, he was made Chief of the Long-Range Radio Branch. In these capacities from 1946 to 1957, he was responsible for research and development of the Army long-distance radio communication equipment and systems. He joined the RamoWooldridge Division of Thompson Ramo Wooldridge Incorporated, Los Angeles, Calif., in 1957 as Co-Head of the Communications Systems Department and is currently employed in that capacity.

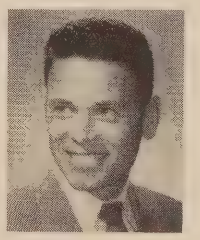
A. B. Moody

Captain Alton B Moody, USNR, was born in Thatcher, Ariz., on July 28, 1911. He graduated from the U. S. Naval Academy, Annapolis, Md., in 1935.

He has had experience in marine navigation in both the Navy and merchant marine, and in air navigation in both the Navy and Air Force. He has taught navigation in private schools and at the Naval Academy. He has been at the U. S. Navy Hydrographic Office since 1946, and for several years has been Deputy Director of the Navigational Science Division. In 1953 he received the international Thurlow Navigation Award for the outstanding contribution to the science of navigation.

Captain Moody is now President of the Institute of Navigation, a government member of the Governing Board of the U. S. Power Squadrons, a member of the Board of Governors of the American Polar Society, and a member of the New York Academy of Sciences and the Arctic Institute of North America.

◆



W. L. Morrison

William L. Morrison (A'52–M'59) was born in Salt Lake City, Utah, on April 3, 1924. After three years as an electronics technician in the U. S. Navy, he attended the University of California, Berkeley, and received the B.S.E.E. degree in 1953.

From 1953 to 1955 he was an electronic scientist at the U. S. Naval Radiological Defense Laboratory, San Francisco, Calif. From 1956 to 1958 he assisted in the design of the first nuclear reactor control console for the Atomic Energy Division of American-Standard, Inc., Mountain View, Calif. He is presently a senior research engineer in the Missiles and Space Division of Lockheed Aircraft Corporation, Palo Alto, Calif.

◆

G. E. Mueller

George E. Mueller (S'39–A'41–SM'46) was born on July 16, 1918, in St. Louis, Mo. He received the B.S.E.E. degree from the Missouri School of Mines, Rolla, in 1939. He continued his education at Purdue University, Lafayette, Ind., where he was a Research Fellow, and obtained the M.S.E.E. degree in 1940. He studied physics at Princeton University, Princeton, N. J., and received the Ph.D. degree in physics from The Ohio State University, Columbus, in 1951. He served as professor of electrical engineering at The Ohio State University for more than ten years.

His technical experience has included television and microwave research at Bell Telephone Laboratories, Holmdel, N. J., and work as a consultant for the Ramo-Wooldridge Corporation, Los Angeles, Calif. He is the author of nine technical publications, and holds six patents in the electron tube and antenna fields. He is presently Vice-President and Associate Director of the research and development division, Space Technology Laboratories, Inc., Los Angeles, Calif.

Dr. Mueller is a member of AIEE and the American Physical Society.

◆

H. L. Newkirk

Horace L. Newkirk was born in Minneapolis, Minn., on June 11, 1911. He received the B.S. degree from Union College, Schenectady, N. Y., in 1933 and the M.S. degree from the University of Idaho, Moscow, in 1940, both in physics. He has since taken additional courses in mathematical physics through the extension program of the University of California at Los Angeles.

From 1940 to 1945 he worked as a physicist in the Navy degaussing program. Since 1945, he has continued as a physicist with the Navy at the Naval Ordnance Test Station, China Lake, Calif., primarily in aeroballistics of rockets.

◆

G. C. Newton, Jr.

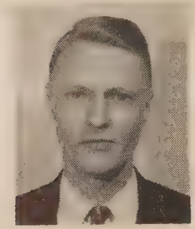
George C. Newton, Jr. (M'47) was born in Milwaukee, Wis., on May 14, 1919. He received the B.S.E.E. degree in 1941 and the D.Sc. degree in electrical engineering in 1950, both from the Massachusetts Institute of Technology, Cambridge. During World War II, he was engaged in defense research and development work at the Special Ordnance Plant in York, Pa., and at the Sperry Gyroscope Company, Inc., Long Island, N. Y.

He is presently Associate Professor of electrical engineering and Associate Director of the Electronic Systems Laboratory at M.I.T. In addition to teaching fundamental electrical engineering subjects and advanced courses in automatic control, he has research interests in the areas of instrumentation, control and computation. His consulting activities include services to both government and industry on military and commercial problems involving electronics and control technology

Dr. Newton is a member of the AIEE, the ASEE, and the Franklin Institute. He received Franklin Institute Levy Medal in 1953.

◆

Robert R. Newton was born on July 7, 1918 in Chattanooga, Tenn. He attended the University of Tennessee, Knoxville, where he received the B.S.E.E. degree in 1940. He received the Ph.D. degree in theoretical physics from The Ohio State University, Columbus, in 1946.



R. R. Newton

For several years he taught in the Physics Departments of the University of Tennessee and Tulane University, New Orleans, La. During this time he also directed a research program in theoretical exterior ballistics for the Ordnance Missile Laboratories, Redstone Arsenal. He joined the Applied Physics Laboratory of The Johns Hopkins University, Silver Spring, Md., in August, 1957, and is now a principal staff member in the field of theoretical physics and supervisor of the Space Exploration Group.

Dr. Newton is a member of the American Physical Society, ARS, Sigma Xi, and Tau Beta Pi.

◆

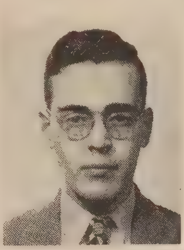
William A. Nichols (M'57) was born in Spartanburg, S. C., on December 28, 1921. He served in the U. S. Marine Corps from January, 1940 to June, 1948 as radio-radar technician and instructor. He was an instructor in the U. S. Navy Electronics Technician Training Program from 1944 to 1947.

W. A. Nichols

He joined the U. S. Naval Research Laboratory, Washington, D. C., in November 1948. He has been responsible for the design and development of electronic instruments and telemetering facilities to implement rocket and satellite probes studying radiations of solar and other celestial bodies in the ultraviolet and X-ray regions. At present, he is Head of the Electrical Design and Engineering Section of the Upper Air Physics Branch.

◆

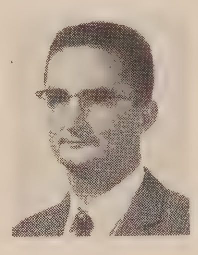
Joseph C. Nowell was born in Boston, Mass., on December 18, 1924. He received the B.S. degree in 1948, and the M.S. degree in 1950, both from Massachusetts Institute of Technology, Cambridge, Mass. He remained at M.I.T. to work on missile control systems in the Dynamic Analysis and Control Laboratory, and subsequently on missile guidance and advanced radar techniques in the Research Laboratory of Electronics. He is now with the Advanced Development Department of the Missile Systems Division, Raytheon Manufacturing Company, Bedford, Mass.



J. C. Nowell

◆

Douglas D. Ordahl was born on April 17, 1921, in Santa Rosa, Calif. He received the B.S. degree in chemistry from Stanford University, Stanford, Calif., in 1942, and the M.S. degree in chemical engineering from The Ohio State University, Columbus, in 1948.



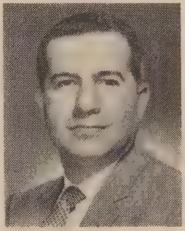
D. D. Ordahl

He entered the propulsion field in 1942 at the Hercules Powder Company, Radford, Va., and in 1945 became a research engineer at Battelle Memorial Institute, Columbus, Ohio. In 1950, he joined the Naval Ordnance Test Station, China Lake, Calif., in order to continue research on the physical properties of solid propellants. He is presently Associate Head of the Propulsion Development Department there and does research, design, development and program direction of solid-, liquid-, ramjet-, and hybrid-propulsion systems.

Mr. Ordahl is a member of Phi Lambda Upsilon, ARS, and the American Chemical Society.

◆

Merwin B. Pickover was born in New York, N. Y., October 8, 1929. He received the B.E.E. degree from the College of the City of New York in 1951.



M. B. Pickover

He was project engineer with the Bendix Corporation, Teterboro, N. J., and was transferred to the Red Bank division in 1952. His responsibility as project engineer was the design of missle and aircraft electrical accessories. In 1958, he joined the U. S. Army Signal Research and Development Laboratory, Fort Monmouth, N. J. As senior engineer, he now heads the team engaged in the design and development of tape recorder circuitry for satellite instrumentation; particularly, transistorized controls on recorder motors, for specialized applications as well as associating circuitry. At this time he is assigned to the Astro-Instrumentation Branch, Astro-Electronics Division, USASDRL.

◆

Norman S. Potter (SM'58) was born in New York, N. Y., on November 5, 1926. He received his undergraduate training at Brooklyn College, Brooklyn, N. Y., and at the U. S. Naval Academy, Annapolis, Md., where he studied marine and electrical engineering. He received the B.A. degree in mathematical physics from Brooklyn College in 1945 and the M.S. degree in applied mathematics and physics from Massachusetts Institute of Technology, Cambridge, in 1953. He continued supplementary studies at M.I.T. and Columbia University, New York, N. Y., for the Doctorate Degree.

N. S. Potter

As a member of the research staff, Columbia University, he was associated with the Manhattan Project, where he performed analytic studies in radiation propagation. Later a member of the research staff of the Department of Electrical Engineering at M.I.T., he worked for some years on SAGE system development, electron digital computer logic, data handling in real-time problems, advanced target acquisition techniques, and general air defense systems analyses. Following this, he was affiliated with The Martin Company for several years as a senior engineer in the field of advanced design, with primary responsibility for systems studies in several categories of missiles, airborne fire control systems, missile guidance techniques, and the analysis of composite airborne electronics subsystems.

He then served as a consultant at USAF Headquarters in Europe in the field of technical evaluation of foreign airborne weapons systems. Following his return from Europe, he was with the Air Arm Division of Westinghouse where, for several years as a Fellow Engineer and Weapons Systems Group Leader, he had primary responsibility for systems analyses and development in air-launched guided missiles, bomber detection and penetration techniques, airborne early warning and interceptor-borne detection and tracking equipments, advanced automatic acquisition techniques in discrete data systems, and operations analysis in large-scale air defense system evaluations.

For some years he has been engaged as a special consultant on guided missiles systems to the Assistant Chief of Staff, Intelligence, Department of the Army, and is presently manager of the Weapons Systems Research Laboratory of the Research and Development Division of the W. L. Maxson Corporation, New York, N. Y., where he is concerned with advanced systems studies in all phases of military and industrial electronics.

He is a member of the IAS, ARS, and AAAS.

❖

J. Praglin

Julius Praglin (M'56) was born in Boston, Mass., on June 12, 1927. He received the B.A. degree in biology from Clark University, Worcester, Mass., in 1948, and the M.S. and Ph.D. degrees in physiology from the University of Illinois, Urbana, in 1950 and 1952, respectively.

From 1952 to 1955, he was engaged in research on the biophysics of vision at Western Reserve University, Cleveland, Ohio. In 1955, he joined Keithley Instruments, Inc., Cleveland, Ohio, as director of Research and Development. He became a Vice-President of Keithley Instruments in 1957 and presently is in charge of Research and Engineering.

Dr. Praglin is a member of Sigma Xi.

❖

A. V. Pratt

A. V. Pratt was born in Maupin, Ore., on July 4, 1924. He received the B.A. degree from the University of California, Berkeley, in 1950 and has since done graduate work at the University of Utah, Salt Lake City, and the University of Colorado, Boulder.

He has worked for the U. S. Naval Ordnance Test Station, China Lake, Calif., since 1950 and is presently serving as a physicist in the Weapons Development Department there.

❖

A. G. Ratz

Alfred G. Ratz (M'49) was born in Hamilton, Can., on April 20, 1922. He received the B.A.Sc. degree in 1944, the M.A.Sc. degree in 1947, and the Ph.D. degree in 1951 from the University of Toronto, Can.

From 1947 to 1949, he was lecturer in electrical engineering at the University of Toronto. For the next three years, he was project engineer at the University's Computation Center where he did basic development work on digital computer techniques, culminating in the building of a digital computer. From 1952 to 1957, he was engaged in airborne electronic systems work at the Air Armament Engineering Department of Canadian Westinghouse. As a project engineer on air-to-air missile electronics, he was responsible for the development circuitry, subminiaturization, ruggedization, reliability and packaging of guidance systems. Subsequently, as section engineer and manager of the Systems Section, he directed a wide range of airborne projects, including guidance, control, aerodynamics, countermeasures, and planning and execution of missile flight tests and firings. In 1957, he joined the Applied Science Corporation of Princeton, Princeton Junction, N. J., where as assistant manager of the Engineer Planning Department he directed the study, research and development of pioneer telemetering hardware, including statistical telemetering devices. In January, 1959, he was appointed chief engineer. He joined Gulton Industries, Inc., in June, 1959, as Chief Engineer of the new Ortholog Division specializing in instrumentation, telemetry, and data-handling systems.

❖

H. B. Riblet

Henry B. Riblet (SM'44) was born on May 20, 1911, in Clayton, N. M. He graduated from Friends University, Wichita, Kans. in 1934 with a B.A. degree in physics and chemistry.

After graduation, he worked at radio station KLZ in Denver, Colo., as chief transmitter engineer. In 1940, he joined the consulting radio engineering firm of Glenn D. Gillett, Washington, D. C., where he was engaged in design and adjustment of directional antennas for radio broadcasting stations. During World War II, he was a member of the Research and Development Staff at Airborne Instruments Laboratory directed by Columbia University, New York, N. Y., where he was engaged in the development of airborne magnetic detection for submarines. After the war, he rejoined the Glenn D. Gillett firm. In March, 1949, he joined the staff of The Johns Hopkins University, Applied Physics Laboratory, Silver Spring, Md., to work with the Telemetering Group. In 1950, he was appointed Group Supervisor of the Telemetering Group, later known as Instrumentation Development. Recently, he has been the supervisor of an Electronics Group conducting development and engineering for satellite instrumentation.

❖

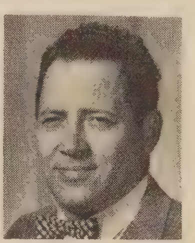
Robert W. Rochelle (S'46–A'50–M'58) was born on June 23, 1923, in Nashville, Tenn. He received the B.S.E.E. degree from the University of Tennessee, Knoxville, in June, 1947, and the Master of Engineering degree from Yale University, New Haven, Conn., in 1949. He began graduate studies at the University of Maryland, College Park, and taught in their graduate program for two years.

R. W. Rochelle

In March, 1949, he joined the Naval Research Laboratory, Washington, D. C., where he participated in the development of electronic instrumentation for the Pacific nuclear test. In 1956, he joined the Magnetic Amplifier Section, where he designed a telemetry system for the Vanguard satellite program. In November, 1958, he was transferred to the National Aeronautics and Space Administration and became head of the Flight Data Systems Branch, Payload Systems Division. He is currently working on electronic instrumentation for satellites and space probes.

Mr. Rochelle is a member of Tau Beta Pi, RESA, and AAAS.

❖



J. L. Ryerson

Joseph L. Ryerson (A'55–M'55) was born on October 20, 1918, in Goshen, New York. He received the B.E.E. degree from Thomas S. Clarkson College of Technology, Potsdam, N. Y., in 1941 and the M.A.E.E. degree from Syracuse University, Syracuse, N. Y.

Upon graduation he was employed as a development engineer by the Ward Leonard Electric Co. of Mt. Vernon, N. Y. In 1946, he was employed by the Associated College of Upper New York as a Professor of physics and later transferred to Evansville College, Evansville, Ind., as a Professor of physics and electrical engineering. Here, in addition to teaching, he became a registered professional engineer and entered the consulting field. Employed as an electronics engineer by the Rome Air Development Center, Rome, N. Y., in 1951, he was assigned the problem of investigating automatic landing. He is now the Senior Scientist, Office of Advanced studies, there.

Mr. Ryerson is a member of Sigma Phi Sigma.

❖

Charles Saltzer (M'56) was born on February 13, 1918, in Cleveland, Ohio. He studied mathematics and physics at Western Reserve University, Cleveland, Ohio, the University of Illinois, Urbana, the University of Nebraska, Lincoln, and Brown University, Providence, R. I. At Brown University he received the doctorate degree in applied mathematics in 1949.

He worked in gas dynamics at Brown University from 1943 to 1945 and was an instructor of mathematics from 1945 to

1948. He was appointed instructor of mathematics at Case Institute of Technology, Cleveland, in 1948 and subsequently to the positions of assistant professor and associate professor. He is on partial leave of absence and holds the position of Consulting Engineer at Thompson Ramo Wooldridge Inc., Cleveland. He was appointed professor of applied mathematics at the University of Cincinnati, Ohio, in 1960.

C. SALTZER

He was retained by the General Electric Company as a consultant in information theory and computer design from 1956 to 1958. He has also done consulting work in numerical analysis, biophysics and space technology, and has published papers on electrical network theory, switching theory, distributions and numerical analysis. He spent a year in England (1950–1951) on a Fulbright Exchange. He received a National Science Foundation Award for research on Finite Difference Operators in 1959.

Dr. Saltzer is a member of the American Mathematical Society, the American Mathematical Association, the London Mathematical Society, the Association for Computing Machines, the Society for Symbolic Logic, the ARS, and Sigma Xi.

* * *

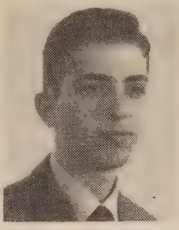
William F. Sampson was born in Oak Park, Ill., on July 6, 1929. He received the B.S. degree in physics from the California Institute of Technology, Pasadena, in 1951.

W. F. SAMPSON

He then joined the research staff of Jet Propulsion Laboratories at the California Institute of Technology. During his six years there, he took a leading part in the development and field testing of the Microlock Receiving System used in the Explorer satellite program. In 1957, he became head of the Space Communications section of Hallamore Electronics Company, in Anaheim, Calif. He directed the development of several subsystems for advanced telemetry systems; supervised the design, installation and check-out of tracking stations; and directed systems integration projects for space probe tracking and guidance complexes. He was then promoted to engineering manager, and directed research programs and corporate projects related to advanced systems. In November, 1959, he joined Space Technology Laboratories, Los Angeles, Calif., where he is a senior staff engineer in the Telecommunications Laboratory.

Mr. Sampson is a member of Tau Beta Pi and of Sigma Xi.

Allen A. Sandberg was born in New York, N. Y., on August 15, 1938. A senior at Massachusetts Institute of Technology, Cambridge, Mass., he expects to receive the B.S.E.E. and M.S. degrees in June, 1961.

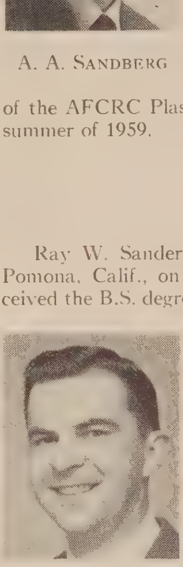


A. A. SANDBERG

Through participation in the electrical engineering, cooperative program at M.I.T., he was a student member of the AFCRC Astrosurveillance Sciences Laboratory in 1958 and of the AFCRC Plasma Physics Unit in the summer of 1959.

* * *

Ray W. Sanders (SM'59) was born in Pomona, Calif., on April 24, 1927. He received the B.S. degree in physics and mathematics from Stanford University, Stanford, Calif., in 1948, and the M.S.E.E. degree from Stanford in 1950. From 1950 to 1951, he was an acting instructor and research assistant at Stanford.



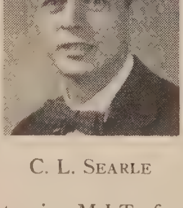
R. W. SANDERS

From 1951 to 1958, he worked at Gilfillan Bros., Inc., Los Angeles, Calif. in the fields of missile systems analysis and design, missile flight tests, air traffic control systems, automatic electronic countermeasure systems, and air navigation system analysis. While at Gilfillan, he served as Director of the Missile Section in the Engineering Department. He is presently with Space Electronics Corporation, Glendale, Calif., where he is Manager of the Space and Satellite Systems Department.

Mr. Sanders is a member of Sigma Xi and the American Ordnance Association.

* * *

Campbell L. Searle (S'46–A'48–M'55) was born in Winnipeg, Can., on July 24, 1926. He received the B.S.E.E. degree at Queens University, Kingston, Ontario, Can., in 1947, and the M.S. degree at the Massachusetts Institute of Technology, Cambridge, in 1951.



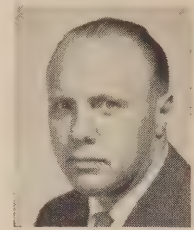
C. L. SEARLE

From 1948 to 1955, he was engaged in electronics research in the guided missile field at the Research Laboratory of Electronics, M.I.T., first as a research assistant and later, as a staff member of the Division of Sponsored Research. He joined the M.I.T. teaching staff in 1956, and is now an assistant professor in the Department of Electrical Engineering.

Mr. Searle is a member of Sigma Xi.

* * *

George F. Senn (SM'50) was born on May 11, 1913 in Philadelphia, Pa. He received the B.S.E.E. degree from Drexel Institute of Technology, Philadelphia, in 1935.



G. F. SENN

In 1935 he was with Philco Radio and Television Co. in Philadelphia and in 1936 with Radio Corporation of America in Camden, N. J. In 1937, he joined the U. S. Army Signal Research and Development Laboratory at Fort Monmouth, N. J., and since that time has been Chief of the Vehicular Installation Section, Chief of the Quality Control Division, and is currently the Chief Engineer of the Communications Department. In 1958, he was the project manager in charge of the "SCORE" Communications Satellite Project.

* * *

Arthur E. Sherburne (S'49–A'51–M'56) was born in Tyngsboro, Mass., on August 20, 1923. He received the B.S.E.E. degree from Tufts University, Medford, Mass., in 1950 and the M.S.E.E. degree from Massachusetts Institute of Technology, Cambridge, in 1951.

A. E. SHERBURNE

Since 1951, he has been employed at Trans-Sonics, Inc., Burlington, Mass., where he contributed to the development of airborne radar systems and in 1956 supervised the flight testing of a radar system. In 1958, he directed the development of an acoustic phase detector for Lox and JP-4. He has been a member of the New Product Research Department since its creation in 1958.

Mr. Sherburne is a member of Tau Beta Pi and Sigma Xi.

* * *

Frederick F. Slack was born in Lawrence, Mass., on June 16, 1917. From 1941 to 1945, he was engaged in research and development at M.I.T. Radiation Laboratory, Cambridge, Mass., and was granted several patents on radar indicator circuits. In 1945, he joined a newly formed organization which is now known as the Air Force Cambridge Research Center. As section chief in the Air Traffic Control Laboratory, he was responsible for the design and development of the first complete automatic track-while-scan unit for the VOLSCAN system. In connection with this work he invented the "light gun" for the acquisition of radar targets and assignment of automatic tracking gates. The light gun has since been adopted by a number of agencies for application in military radar systems, among them the SAGE system.

F. F. Slack

He is now chief of the Development Section of the AFCRC Astrosurveillance Sciences Laboratory, Bedford Mass. Dealing with special systems, he has developed the Cartesian coordinate automatic tracking system (CARTRAC) for the Tactical Air Command, designed a semiautomatic intercept computer (SAINT), and, more recently, evolved techniques for detecting the launching of missiles and satellites.

❖

Richard J. Slifka was born in Milwaukee, Wis., September 10, 1927. He received the B.S.E.E. degree from the University of Wisconsin, Madison, in 1951.

R. J. Slifka

After graduation, he joined the AC Spark Plug Division of the General Motors Corp., Milwaukee, Wis., as a service engineer. In this capacity, he was associated with the Gunsight and Bombing Navigational Computer projects. In 1956, he joined the AC Spark Plug Engineering Department, in which his projects included test planning and coordination of field sites for the inertial guidance equipment for the Thor Missile. He is now a senior project engineer, responsible for field operations for the inertial guidance equipment for the Thor Missile.

Mr. Slifka is a member of the AIEE.

❖

Alex G. Smith was born in Clarksburg, W. Va., on August 12, 1919. He received the B.S. degree in physics from the Massachusetts Institute of Technology, Cambridge, in 1943. During the remainder of the war, he worked at the M.I.T. Radiation Laboratory on magnetron development, and participated in the writing of a volume of the Radiation Laboratory Series. In 1948, he received the Ph.D degree in physics at Duke University, Durham, N. C., for which he wrote a dissertation on microwave spectroscopy.

A. G. Smith

Since that time he has been at the University of Florida in Gainesville, where he has held the ranks of assistant professor, associate professor, and, currently, full professor of physics. His research interests at the University have included microwave spectroscopy, military VHF electronics development, atmospheric optics, and low-frequency planetary radio astronomy.

Dr. Smith is a member of Sigma Xi, the American Physical Society, the American Optical Society, the American Astronomical Society, and the Astronomical Society of the Pacific.

❖

Robert T. Smith (M'56) was born in Kansas City, Mo., on October 25, 1930. He received the B.S.E.E. degree from the University of Kansas, Lawrence, in 1952, and while there he was employed by the University of Kansas Research Foundation on an analog computer development project.

R. T. Smith

Upon graduation, he joined the U. S. Naval Ordnance Test Station, China Lake, Calif., where he worked on air-to-ground fire control systems, special weapon fuzing systems, and automatic process control systems. In 1956, he assumed the responsibility of program manager for an airborne fire control program. He joined the Philco Western Development Laboratories, Palo Alto, Calif., in 1958, and is now manager of the advanced applications section of the satellite systems department. His current activities are in the analysis and design of current and proposed space electronic programs.

Mr. Smith is a member of Eta Kappa Nu and Sigma Tau.

❖

Roy C. Spencer (M'46–SM'50–F'60) was born on April 14, 1901 in Pennellville, New York. He received the B.A. degree from Cornell University, Ithaca, N. Y. in 1922, and the Ph.D. degree in physics from Columbia University, New York, N. Y., in 1932.

R. C. Spencer

From 1922–1923, he was a Fellow in Astronomy at Swarthmore, College, Swarthmore, Pa., and from 1923–1924, a Hechscher assistant in X rays at Cornell University. In 1926 and 1927, he was a Radio Tube Development engineer at the Westinghouse Lamp Co., Bloomfield, N. J. From 1927 to 1931, he was an instructor in physics at Columbia University, and from 1931 to 1941, he held positions of instructor, assistant professor and associate professor of physics at the University of Nebraska, Loncoln.

In 1941 he was granted a leave of absence from the University of Nebraska to become a staff member of the Radiation Laboratory of the Massachusetts Institute of Technology, Cambridge, Mass., where he carried out research on microwave antennas and diffraction theory. He was chief of the Antenna Laboratory of the Air Force Cambridge Research Center, Bedford, Mass., from 1946 to 1955, when he joined the Sylvania Missile Systems Laboratory, Waltham, Mass., as a senior engineering specialist and consultant. In 1958, he joined the Martin Company, Baltimore Division, Baltimore, Md., as principal staff scientist.

Dr. Spencer is a Fellow of the American Physical Society and the AAAS, and a member of the American Optical Society, the American Mathematical Society, Sigma Xi, and RESA (Research Society of America). He served on the U. S. National Committee of Commission VI of URSI and was a U. S. delegate to three International Assemblies in 1952, 1954, and 1957.

❖

James O. Spriggs (M'60) was born in Syracuse, N. Y., on May 18, 1914. He received the B.A. degree in sociology in 1936, the LL.B degree in 1940, and the B.A. degree in physics in 1945, all from Syracuse University, Syracuse, N. Y. He is a member of the New York State Bar.

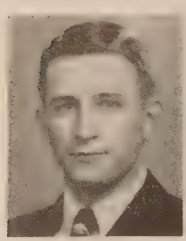
J. O. Spriggs

From 1940 to 1942, he practiced law with Spriggs, Merry, and Hartman of Syracuse. He was engaged in research and development in the fields of direction finding and countermeasures at the Naval Research Laboratory, Washington, D. C., from 1942 to 1949, receiving the Meritorious Civilian Service Award in 1946. From 1949 to 1958, he was in the Office of the Secretary of Defense, first in the Research and Development Board, the Office of the Assistant Secretary for Research and Development, and then the Office of the Director of Guided Missiles. Since 1958, he has been on the staff of the Advanced Research Projects Agency in the ballistic missile defense and space fields as Special Assistant to the Chief Scientist, to the Deputy Director, and, most recently, as Program Manager for the Courier communications and the Transit navigation satellite project.

❖

R. E. Stalcup was born in Bloomfield, Ind., on February 19, 1927. He received the B.S.E.E. and M.S.E.E. degrees from Purdue University, Lafayette, Ind., in 1950 and 1959, respectively. He is now working on the

Ph.D. degree at the University of Illinois, Urbana.



R. E. Stalcup

After receiving the B.S.E.E. degree, he joined ITT Laboratories, Fort Wayne, Ind., where he has done research and development in the following fields: design and development of magnetic amplifiers for servo applications and for computing devices; design of radio and television circuitry; design and development of digital computer circuitry, a radar system test set and fuze test set; Terrier and Bomarc missile programs; analysis, design and development of aircraft fire-control systems; studies pertaining to the use of radiometers in guidance systems; and analysis of infrared attitude control system for space vehicle (orbiting) and studies of applicability of Doppler radar to terminal guidance problems of space vehicles.

❖

A. R. Tanguay

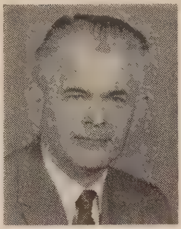
Armand R. Tanguay (S'49–A'51–SM'57) was born in Beloeil, Quebec, Can., on February 1, 1924. He received the B.S.E.E. degree from the University of Massachusetts, Amherst, in 1950 and the M.S.E.E. degree from the Massachusetts Institute of Technology, Cambridge, in 1951. While at M.I.T., he was a research assistant at the Digital Computer Laboratory (Project Whirlwind) doing research on electrostatic storage tubes.

From 1951 to 1957, he was employed at the Cornell Aeronautical Laboratory, Buffalo, N. Y. He was Associate Research Engineer from 1951 to 1955, concerned with research and development of military electronic systems and responsible for development of advanced missile ground guidance equipment. From 1955 to 1957, he was head of the Systems Analysis Section in the Weapons Systems Design Department, responsible for analysis, evaluation and data processing for the Lacrosse missile program, as well as for studies on advanced missile systems. Now with Radiation Incorporated, Orlando, Fla., he is Head of the Systems Research Department, with responsibility for advanced missile systems, space vehicle systems and guidance studies, computer simulation, and research in automation.

Mr. Tanguay is a member of Phi Kappa Phi and a senior member of the American Astronautical Society and Sigma Xi.

❖

Frederick J. Tischer (SM'55) was born on March 14, 1913, in Plan, Austria. He received the Ph.D. degree from the University of Prague, Czechoslovakia, in 1938, and did advanced study at the University of Berlin, Germany.



F. J. Tischer

Before coming to the United States in 1954, he directed activities in microwaves at the Royal Institute of Technology, Stockholm, Sweden. He headed a research group working on electronic guidance at Redstone Arsenal, Huntsville, Ala., until 1956, when he joined the staff of the Electrical Engineering Department, The Ohio State University, Columbus. He is now an associate professor, and has taught, among other courses, one on space communications for two years. He is the author of "Microwave Measurements," and of numerous articles on communication theory, microwaves, and electromagnetics. He is the inventor of the Ring Resonator, the H-Guide, and several other microwave devices and antennas.

Dr. Tischer is a member of Sigma Xi.

❖

T. H. Vea

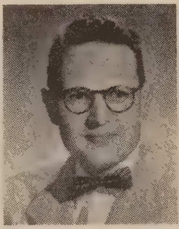
Theodore H. Vea (S'50–A'53–M'59) was born in Canton, Ohio on December 13, 1930. He received the B.S.E.E. degree from the University of Cincinnati, Cincinnati, Ohio, in 1953 where, on the cooperative engineering program, he was employed by the Wright Air Development Center in the search radar branch. In 1954–1955, he was an instructor in the electrical engineering department at the University of Pittsburgh, Pittsburgh, Pa., where he received the M.S. degree in 1955.

He has been employed by the Westinghouse Air Arm Division, Stanford Applied Electronics Laboratory, and the General Electric Computer Department where he has worked on airborne fire control systems, electronic countermeasure systems and the development of a data processing system for banking applications. In 1957, he returned to Stanford University to do graduate study and was a Research Assistant in the Radio Propagation Laboratory. In 1959, he joined the Philco Western Development Laboratory, Palo Alto, Calif., where he is employed as a project engineer in the advanced applications section of the satellite systems department. His activities include the analysis and design of communication systems for satellite applications.

Mr. Vea is a member of the American Institute of Physics, the Association for Computing Machinery, and AIEE.

❖

Joseph H. Vogelman (M'46–SM'49–F'59) was born in New York, N. Y., on August 18, 1920. He received the B.S. degree in 1940 from the College of the City of New York, N. Y., and the M.S. and Ph.D. degrees in 1948 and 1957, respectively, from the Polytechnic Institute of Brooklyn, N. Y., both in electrical engineering.

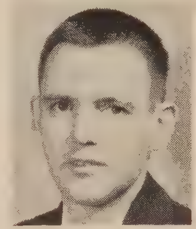


J. H. Vogelman

In 1945, after several years at the Signal Corps Radar Laboratory at Ft. Hancock and Belmar, N. J., he joined the staff of the Watson Laboratories, Red Bank, N. J., where he served as Chief of the Development Branch until 1951, responsible for research and development of test equipment and microwave components and techniques. In 1951, he moved to the Rome Air Development Center, Griffiss Air Force Base, Rome, N. Y. From 1951 to 1953, he was Chief Scientist in the General Engineering Laboratory and consultant on UHF and SHF theory and techniques to the Air Force. From 1953 to 1956, he was Chief of the Electronic Warfare Laboratory, directing all research and development in ground-based electronic warfare for the Air Force. From 1956 through June, 1959, he was Technical Director of the Communications Directorate with responsibility for the Air Force research and development effort in ground-based and ground-to-air communications. He is now Director of Research and Development at Dynamic Electronics Division, Capehart Corporation, Richmond Hill, N. Y.

Dr. Vogelman is a Fellow of the AAAS and a member of Eta Kappa Nu, Sigma Xi, the AIEE, and the Armed Forces Communications and Electronics Association.

❖



J. M. Walter, Jr.

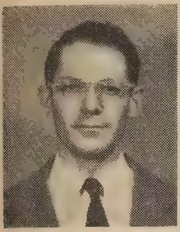
James M. Walter, Jr. (S'54–M'56) was born on March 13, 1931 in Harrodsburg, Ky. He received the B.E.E. degree from the University of Florida, Gainesville, in 1956.

After serving with the U. S. Navy for four years as an aviation electronic technician, he joined Radiation, Inc., Melbourne, Fla., in 1956. His work there has included participation in low-level electronic subcommutation, 250-channel multiplexer, RADICON, RADIAN, AFMTC Timing Terminal Equipment, PDM to digital coder and PPM to digital coder developments. He has recently been engaged in the development of a 96-channel digital data acquisition system for NORAIR and the acquisition system reported on in this issue.

Mr. Walter is a member of Sigma Tau and Phi Eta Sigma.

❖

George C. Weiffenbach was born on June 20, 1921 in Newark, N. J. He attended Harvard University, Cambridge, Mass. where h obtained the B.A. degree in 1949, and also Catholic University, Washington, D. C., where he obtained the Ph.D. degree in experimental physics in 1958.



G. C. Weiffenbach

He joined the Applied Physics Laboratory of The Johns Hopkins University, Silver Spring, Md., in 1951 and is now a senior staff member in the field of experimental physics.

Dr. Weiffenbach is a member of Sigma Chi, the American Institute of Physics, the American Geophysical Union and the Philosophical Society of Washington, D. C.

❖

William E. Williams, Jr. (SM'55) was born in Hattiesburg, Miss , on April 6, 1921. He received the B.S. degree in physics in 1942 from Mississippi State College.

After graduation, he joined the staff of the National Bureau of Standards where he was engaged in circuit design work on proximity fuzes for bombs and rockets. After a tour of duty in the Army from 1944 to 1946, he returned to the Electronic Instrumentation Section, NBS, where his field of work was in the design of a variety of special-purpose instruments to measure pressure, liquid levels, vibration, and oil film thickness, as well as pulse generators and temperature control equipment. From 1953 to 1956, he was engaged in the design of aircraft flight simulators with primary responsibility for the simulated radar and electronic countermeasures systems. From 1956 to 1959, he was responsible for the design of missile telemetry systems for the Diamond Ordnance Fuze Laboratory. Since then, he has been staff assistant for telemetry in the Office of Space Flight Operations, National Aeronautics and Space Administration.

W. E. Williams, Jr.

Mr. Williams is an associate member of the Telemetry Working Group of the Inter-Range Instrumentation Group.

L. Bruce Wilner was born in Fargo, N. D., on August 7, 1931. He attended Yale University, New Haven, Conn., with the assistance of scholarships, and received the B.E. degree in 1953. He studied at Stanford University, Stanford, Calif., and received an M.S. degree in mechanical engineering in 1954.

L. B. Wilner

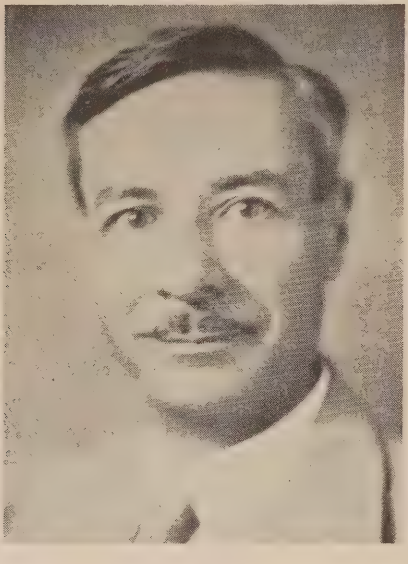
He was employed by Los Alamos Scientific Laboratory for four years and participated in several weapons test operations. In 1958, he was employed by Lockheed Missiles and Space Division, Palo Alto, Calif., and is now working in the Instrumentation Research Group of the Communications and Controls Department at LMSD. His fields of activity have included nuclear component design, gas thermodynamics, and high-pressure technology, relaxation phenomena, and instrumentation for measurements in fluids.

Mr. Wilner is an associate member of ASME.

❖

IRE Awards, 1960

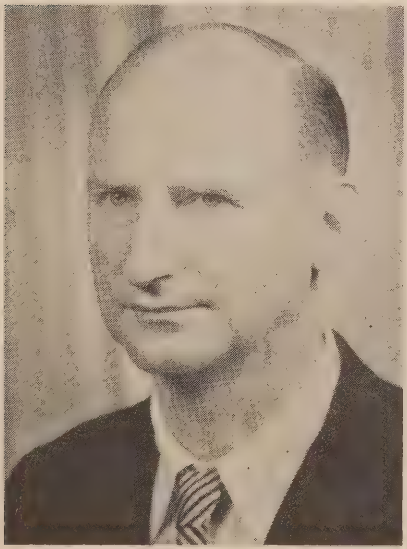
Founders Award



HARADEN PRATT

For outstanding contributions to The Institute of Radio Engineers through wise and courageous leadership in the planning and administration of technical developments which have greatly increased the impact of electronics on the public welfare.

Morris Liebmann Memorial Prize



J. A. RAJCHMAN

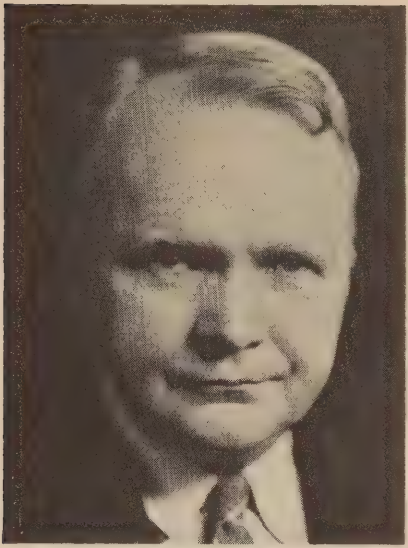
For contributions to the development of magnetic devices for information processing.

Browder J. Thompson Memorial Prize

J. W. GEWARTOWSKI

For his paper entitled "Velocity and Current Distributions in the Spent Beam of the Backward-Wave Oscillator," which appeared in the October, 1958 issue of the IRE TRANSACTIONS ON ELECTRON DEVICES.

Medal of Honor Award



HARRY NYQUIST

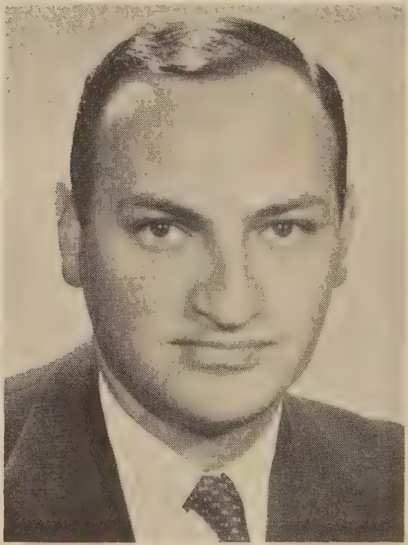
For fundamental contributions to a quantitative understanding of thermal noise, data transmission and negative feedback.

Harry Diamond Memorial Award

K. A. NORTON

For contributions to the understanding of radio wave propagation.

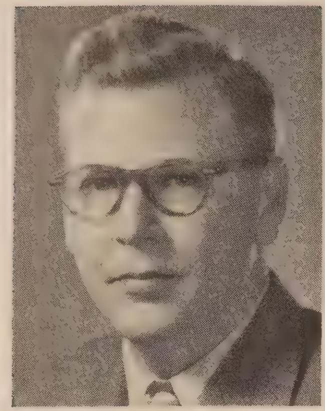
W. R. G. Baker Award



E. J. NALOS

For his paper entitled "A Hybrid Type Traveling-Wave Tube for High-Power Pulsed Amplification," which appeared in the July, 1958 issue of the IRE TRANSACTIONS ON ELECTRON DEVICES.

New Fellows



R. B. Adler

For contributions to engineering education and to research in electronics.

H. H. Aiken

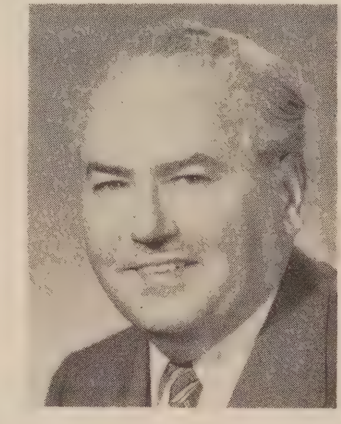
For contributions to the development of computer science and technology.

H. O. G. Alfven

For contributions to the understanding of the properties of plasmas.

W. M. Bailey

For contributions to capacitor technology.



Rudolf Bechmann

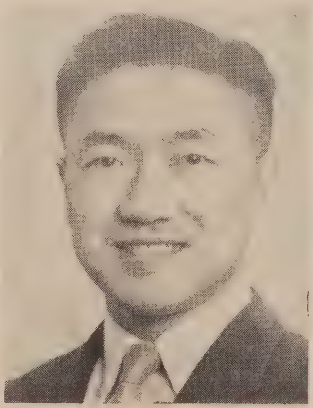
For contributions in the field of piezoelectric crystals.

J. I. Bohnert

For contributions in the field of micro wave antennas.

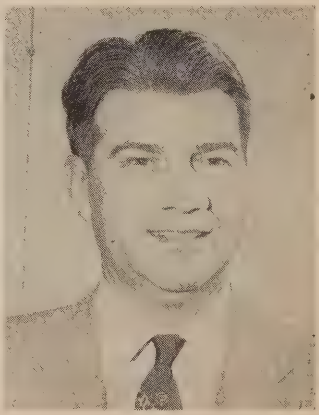
J. F. Calvert

For contributions to electrical engineering and education.



D. K. Cheng

For contributions to engineering education and antenna theory.



Trevor Clark

For contributions to military electronic

New Fellows

P. W. Crapuchettes

For contributions to microwave tube technology.

A. N. Curtiss

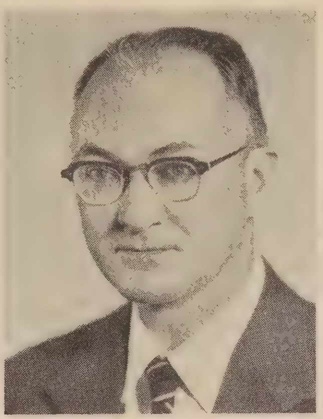
For contributions to radio and radar technology.

C. E. Dean

For contributions in the field of radio and television receivers.

G. A. Deschamps

For contributions to analysis of microwave components.



A. C. Dickieson

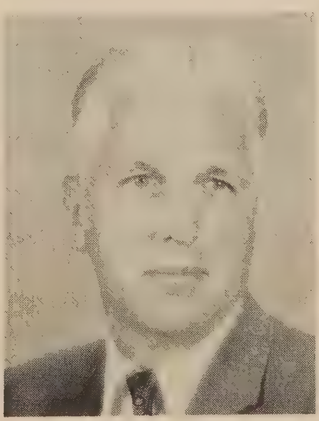
For contributions to wire and radio communications.

Stephen Doba, Jr.

For contributions in the field of television signal transmission.

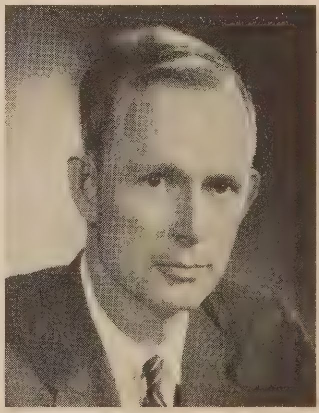
I. G. Easton

For contributions to impedance measuring techniques and equipment.



P. G. Edwards

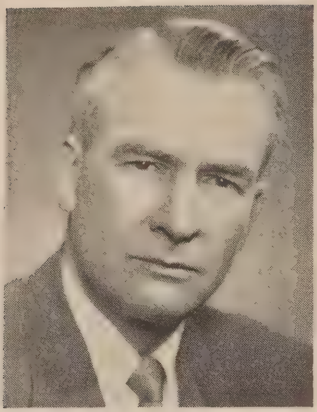
For contributions in the field of telephone communication systems.



J. H. Felker

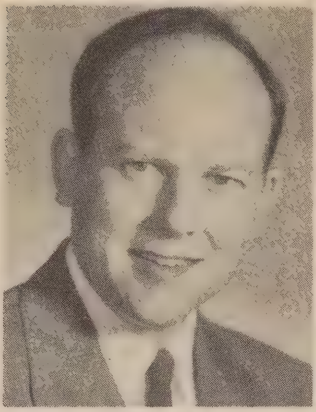
For contributions to computer technology.

New Fellows



G. J. Fiedler

For contributions to electronic process control systems.

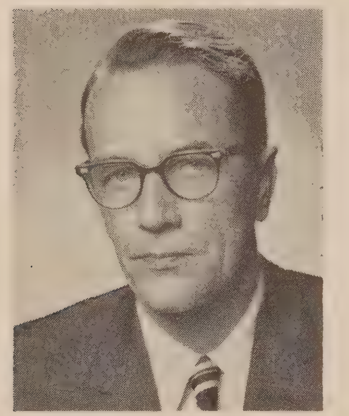


G. A. Fowler

For contributions to atomic energy instrumentation.

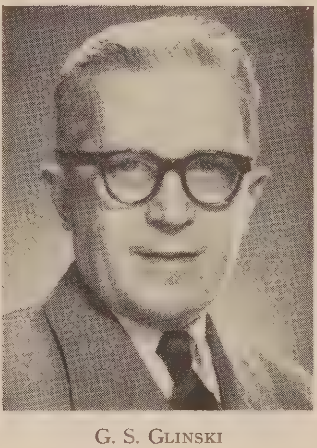
D. W. Fry

For contributions to research in controlled fusion.



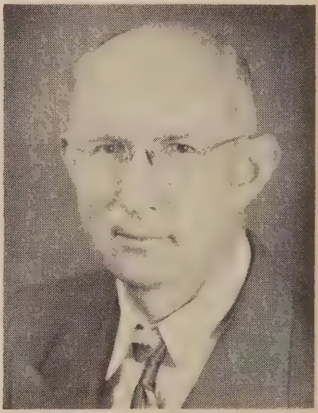
R. W. Gilbert

For application of electronics to measurement techniques.



G. S. Glinski

For contributions to the field of computation.

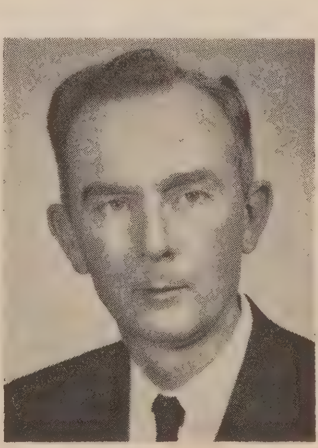


M. J. E. Golay

For contributions to the fields of com munications and infrared technology.

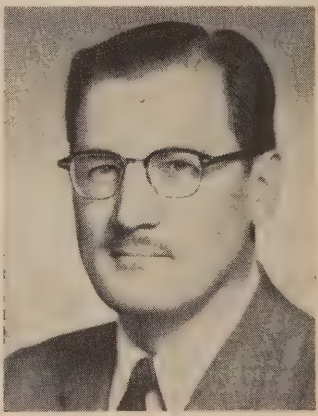
Georges Goudet

For contributions to engineering education and for the administration of research.



W. J. Hamm

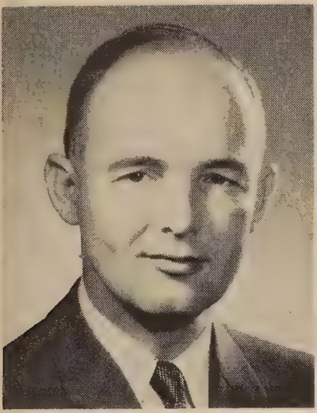
For service in teaching and research.



H. C. Hardy

For contributions to electroacoustics.

New Fellows

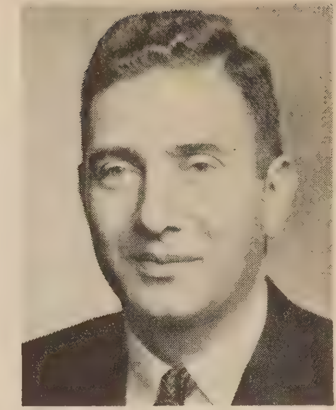


R. A. Helliwell

For contributions to ionospheric radio propagation.

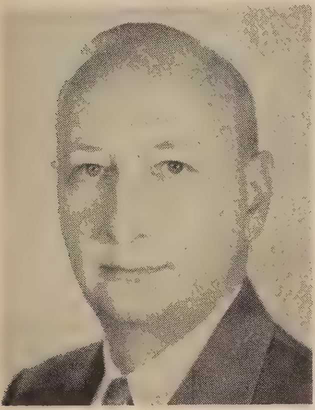
R. K. Hellmann

For work in military electronics.



S. W. Herwald

For contributions to servomechanism technology.



W. H. C. Higgins

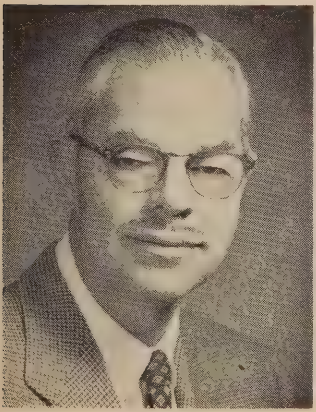
For contributions to military electronics.

C. L. Hogan

For pioneering in the application of ferrites.

J. M. Hollywood

For contributions to electronic countermeasures and color television.



F. L. Hopper

For contributions in underwater sound search and sound recordings

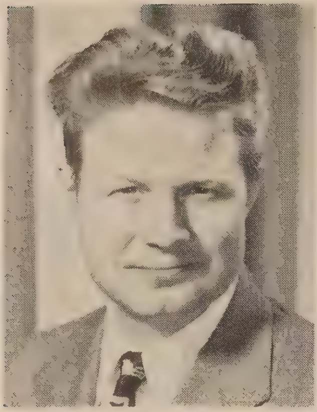
P. W. Howells

For contributions to color television.

H. R. Huntley

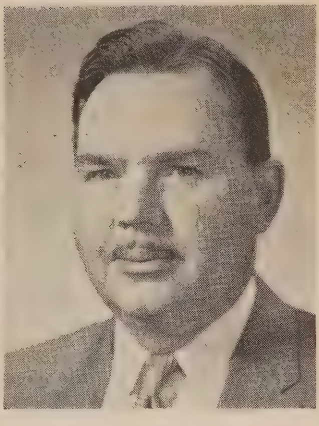
For contributions to communications engineering.

New Fellows



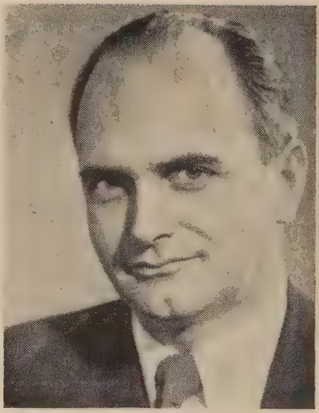
E. O. Johnson

For contributions to gaseous electronics and semiconductors.



Harwick Johnson

For contributions to the development of electron devices.

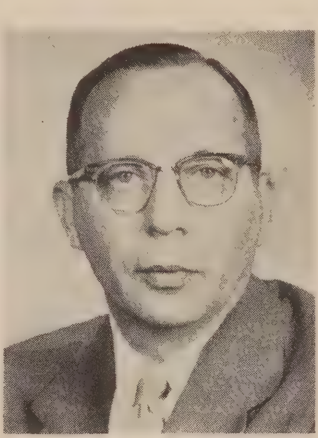


E. A. Keller

For contributions to sound recording and telephone switching systems.

C. L. Kober

For application of electronic techniques to defense systems.



Harry Krutter

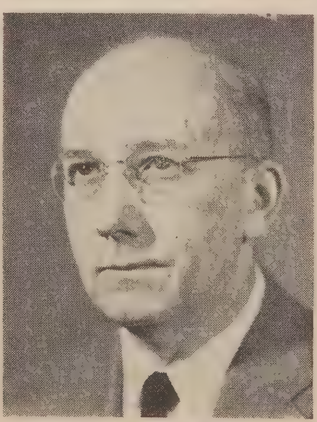
For contributions to defense electronics.

J. G. Linvill

For contributions to network theory and transistor circuits.

W. A. Lynch

For contributions to engineering education.



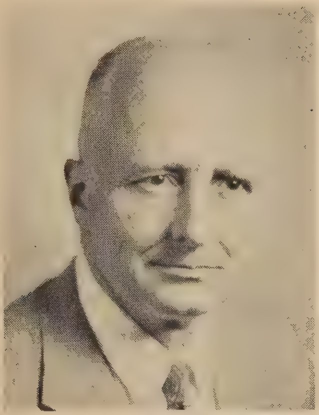
J. M. Manley

For contributions to the theory of modulators and parametric amplifiers.

M. A. McLennan

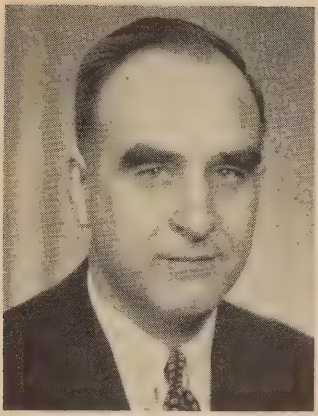
For contributions in aero-medical elec tronics.

New Fellows



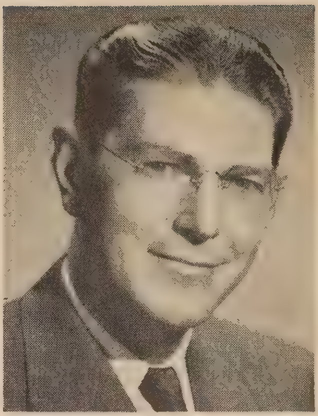
Doren Mitchell

For contributions to long-distance communications systems.



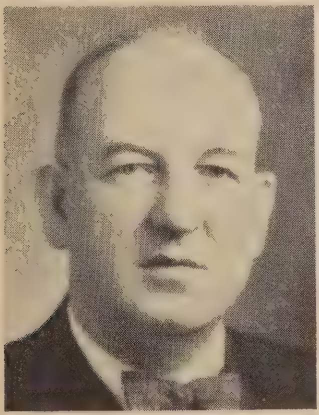
J. P. Molnar

For contributions to gaseous and solid-state electron devices.



L. H. Montgomery, Jr.

For contributions to medical electronics.

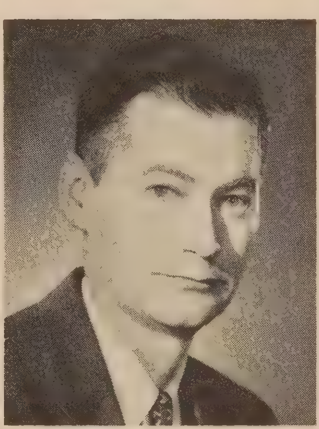


John B. Moore

For improvements in communications coding techniques.

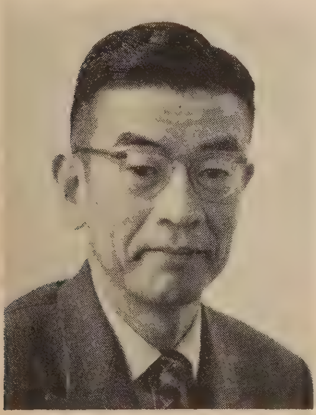
Theodore Moreno

For contributions in the field of microwave electronics.



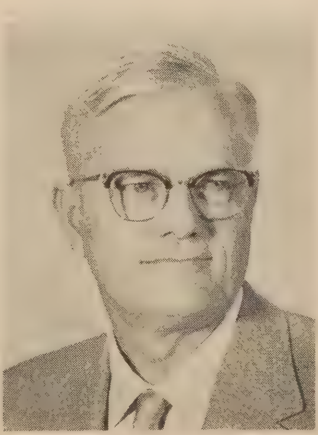
T. H. Morrin

For the administration of research in electronics.



Shogo Namba

For contributions to the understanding of ionospheric radio propagation.



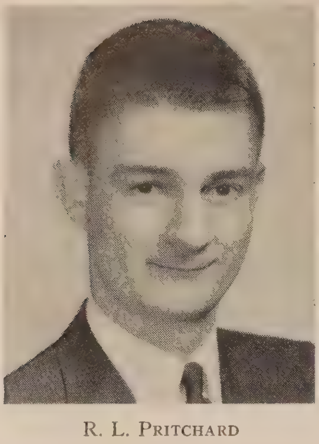
F. R. Norton

For contributions to radar and television.

Franz Ollendorff

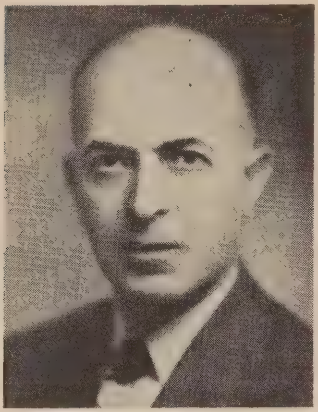
For contributions to electromagnetic theory and engineering education.

New Fellows



R. L. Pritchard

For contributions in the field of transistor circuits



R. L. Rau

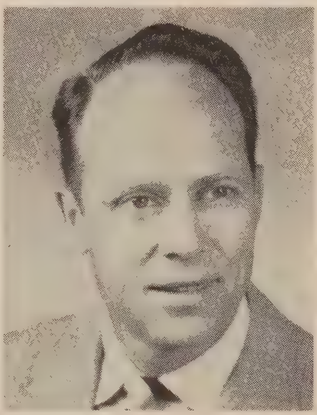
For contributions to international radio communications systems.

L. L. Rauch

For contributions to the theory and practice of radio telemetry.

H. R. Reed

For contributions to engineering education.



V. C. Rideout

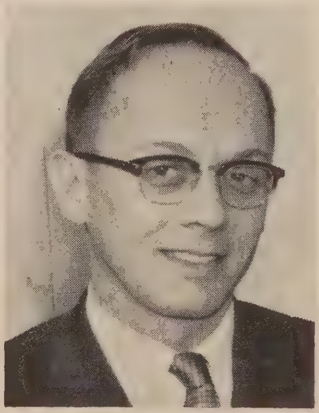
For contributions in the fields of microwave and computer education.

A W Rogers

For contributions in the development of electronic components.

V. H. Rumsey

For contributions to antenna theory and practice.



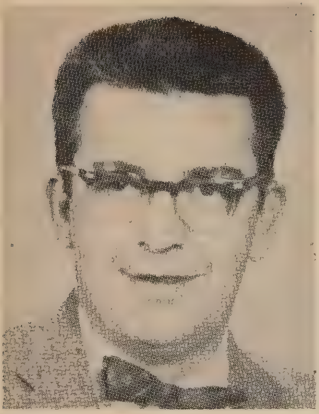
W T. Selsted

For contributions to the art of magnetic recording.

Samuel Sensiper

For contributions in the fields of microwave instrumentation and radiation.

New Fellows



William Sichak

For contributions to the techniques of microwave transmission.

R. L. Sink

For contributions to the field of digital instrumentation systems.

P. T. Smith

For contributions to the development of high-power transmitting tubes.

A. H. Sommer

For contributions in the field of photoemissive surfaces.

R. C. Spencer

, For contributions to the theory of microwave antennas.

W. E. Tolles

For the application of electronics to the field of medicine.

L. G. Trolese

For contributions to the understanding of radio wave propagation.

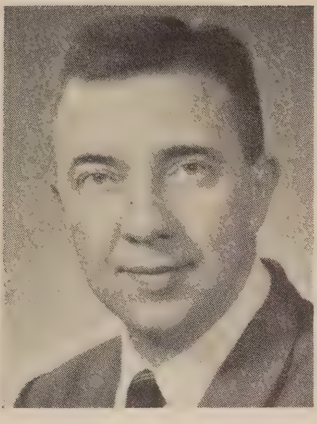
D. F. Tuttle, Jr.

For contributions to network theory and education.

G. E. Valley, Jr.

For contributions to military systems engineering.

New Fellows



J. A. Van Allen

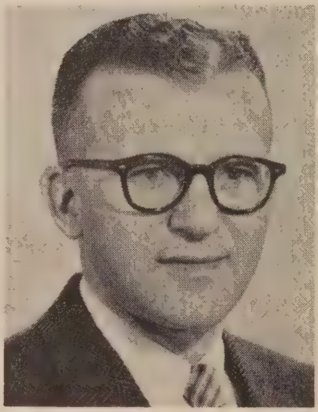
For the experimental discovery and exploration of radiation belts around the earth.

E. A. Walker

For services as an engineering teacher and administrator.

W. M. Webster, Jr.

For contributions to gaseous electronic and solid-state devices.



Louis Weinberg

For contributions to the field of network theory.

Books

Acoustique Musicale, Colloques Internationaux du Centre National de la Recherche Scientifique

Published (1959) by the Editions du Centre National de la Recherche Scientifique, 13, Quai Anatole France, Paris 7^{e}, France. 259 pages. $7\times 8\frac{3}{4}$. (In French.) 3.400 fr.

This volume contains the research papers presented at a three day international colloquium on musical sound, held at Marseille in 1958. One section of ten papers is about musical scales and harmony matters. The other section of thirteen papers is concerned with the physics of stringed and wind instruments. Electronics is involved only in the research instrumentation for spectrum analyses and frequency measurement. Nevertheless, an engineer interested in electronic means for music production, or for music reproduction, will find interesting and worthwhile basic information here about the traditional tone sources and the characteristics of their output waves. Among the musical instruments studied are the violin, cello, guitar, harmonium, pipe organ, French horn, trumpet, flute, clarinet, saxophone, bass horn, piano, and the human voice. The treatment of each instrument could not be comprehensive in one volume (or colloquium), but is illustrative and indicative of the possibilities for further research. The authors are from England, France, Germany, Hungary, Iran, the Netherlands, the USA, and the USSR.

The Baldwin Piano Company
Cincinnati, Ohio

Electron Tube Circuits, by Samuel Seely

Published (1958) by McGraw-Hill Book Co., Inc., 330 W. 42 St., N. Y. 36, N. Y. 657 pages+14 index pages+21 appendix pages+xi pages. Illus. $6\frac{1}{2}\times 9\frac{1}{4}$. $10.50.

This book has been written for electrical engineering students in the fourth year of the electrical engineering curriculum. It consists of some 657 pages exclusive of appendixes and index and is to a large extent identical to the preceding volume (first edition). Some thirty-five pages of new material on semiconductors and transistor circuit applications have been added.

The author covers the same topics that were covered in the first edition with some change in the order and with the material on feedback organized in a separate chapter. There is also some reorganization in the chapters on oscillators and relaxation oscillators. New material has been added, in addition to the treatment of semiconductors and transistors, with respect to feedback and the effect of inverse feedback on the effective internal impedance of an amplifier. The discussion of internal impedance is considerably improved and expanded. The analysis of the cathode follower as a sample of the feedback circuit is very well done. A decided improvement has been made in Chapter 8 in the analysis of the difference amplifier. New material has also been included in the chapter on electronic computer circuits on the solution of simple differential equations. This chapter has 23 problems of which 10 are either identical with or slightly different from the problems in the old text.

Most of the new material is to be found in the expansion of the treatment of electron tube circuits. To a large extent the problems remain unchanged except for the addition of a few problems in most chapters, as for example Chapter 11, Tuned Potential Amplifiers, where the 29 problems include seven new problems added to the original 22 used in the corresponding chapter of the old text. A considerable improvement has been made in portions of the treatment of tuned power amplifiers.

The author makes a somewhat obvious effort to avoid the use of the word voltage, using potential instead. He also uses the term electron tube to refer to and to include all types of electron devices including transistors.

The author provides introductory treatment of the physical basis for semiconductor diode and transistor behavior as circuit components. The space provided for this treatment is not adequate for a satisfactory presentation. His development of the equivalent circuit of the transistor is related to the method used for tube equivalent circuits but is not so complete or satisfying. No mention is made of the h-parameters. Four terminal network theory is not adequately introduced and its usefulness is not made clear.

In summary, the second edition of this text provides a thorough and improved treatment of electron tube circuits. It does not, however, provide an integrated treatment of transistor and tube circuit theory with the proper distribution of emphasis in the semiconductor field.

E. M. BOONE

Information Transmission, Modulation, and Noise, by Mischa Schwartz

Published (1959) by McGraw-Hill Book Co., Inc., 330 W. 42 St., N. Y. 36, N. Y. 454 pages+7 index pages+xv pages. Illus. $6\frac{1}{4}\times 9\frac{1}{4}$. $11.00.

A concomitant of progress in any field is the gradual assimilation of previously esoteric material into earlier and earlier stages of the university curriculum in that field. Thus, in electrical engineering, the almost incomprehensible electromagnetic theory of eighty-five years ago is now meat for sophomores, and juniors and seniors are regularly exposed to the abstrusenesses of the modern form of network theory originating some thirty years ago. We are currently in the process of absorbing into the undergraduate electrical engineering curriculum the fruits of two decades of research into the application of statistical techniques to communication and control system design. The present book is a much-needed step in this process.

At present, a course in probability theory is, unfortunately, not generally required in the beginning years of an electrical engineering education—a situation which assuredly will change. Without the benefit of such a prerequisite course, however, and given only one semester in the senior year in which to teach communication theory, the question is: what should be taught? The answers to this have largely been the unsatisfactory extremes either of concentrating on classical probability theory and statistics, with perhaps some vague indication of the connection of all this abstract basic material to communication systems, or of concentrating on *ad hoc* systems, without giving an underlying statistical approach to the theory of communication systems in general. Professor Schwartz has now given us an excellent compromise solution.

In the first chapter, the author, by relying predominantly on the student's intuitive understanding of probability, gives a very brief introduction to the notions of information content and system capacity. He shows that two principal features of a communication system which limit its ability to transmit information by means of a physical signal are the maximum rate at which it will allow the signal to change, and the number of different signal states which the system can distinguish. The study of these features forms the unifying theme of the book. The first, related to the bandwidth of the system, is investigated in Chapter 2, in which are considered the Fourier analysis of signals and the effects of linear systems on signals. The second is related to the noise in the system, the nature and origins of which are studied in Chapter 5; here, for simplicity, noise is characterized only by its mean and mean-square values, which, defined as time averages, are easily related to the student's previous experience with time averages for nonrandom waveforms.

Chapters 3 and 4 form a detour into the detailed analysis of several conventional information transmission systems, both of the sine-wave (AM and FM) and pulse (PAM and PPM) modulation types. These chapters, interesting per se, are the more so for providing a background for Chapter 6, "Comparative Analysis of Information-Transmission Systems," which in many respects is the *pièce de résistance* of the book. Drawing together the results of the preceding five chapters, the author in this chapter compares the previously discussed conventional systems on the basis of the exchange relationship each exhibits between output signal-to-noise ratio and bandwidth. He shows that although some of these systems are more desirable on this basis than others, none approaches the performance predicted by information-theoretic considerations. This leads to a discussion of coded modulation schemes, and PCM in particular.

A lengthy final chapter is obviously—and both necessarily and regrettably—a postscript to the book, not intended for inclusion in the course. It is a superior, self-contained primer on the use in systems analysis of probability theory and statistics, the details of which had previously been avoided.

Professor Schwartz writes very lucidly indeed. He makes especially deft use of heuristic and intuitive arguments to focus attention on fundamentals and to clarify topics which are apt to be conceptually confusing for the beginner. Inevitably, there are a few minor features of organization with which this reviewer might disagree, and a modicum of those errors to which books, no matter how carefully written, seem to be prone. But in view of the over-all excellence of the book, to dwell on these would be mere carping. To those seeking a text which gives an elementary engineering insight into modern communication theory, this book is most highly recommended.

G. L. Turin
Hughes Research Labs.
Culver City, Calif.

Advances in Space Science, Volume I, Frederick I. Ordway, III, Ed.

Published (1959) by Academic Press, Inc., 111 Fifth Ave., N. Y. 3, N. Y. 382 pages+16 index pages +14 appendix pages+xii pages. Illus. $6\frac{1}{4}\times9\frac{1}{4}$. $12.00.

The book is a collection of six articles and an appendix by separate authors. These are:

1. Interplanetary Rocket Trajectories—by Derek F. Lawden
2. Interplanetary Communications—by J. R. Pierce and C. C. Cutler
3. Power Supplies for Orbital and Space Vehicles—by John H. Huth
4. Manned Space Cabin Systems—by Eugene B. Konecci
5. Radiation and Man in Space—by Herman J. Schaefer
6. Nutrition in Space Flight—by Robert G. Tischer

Appendix. A Decimal Classification System for Astronautics—by Heinz Hermann Koelle.

It is written for the space scientist who may be a specialist but desires to have a working knowledge of his associated fields. By existing standards it represents a rather thorough treatment of each of the six subjects presented. Much of the material in the first chapter was prepared as a report by Radiation Incorporated on an Air Force contract. Trajectories are considered mainly as a transfer between orbits which is generally predicated upon minimum propellant consumption and minimum time of flight criteria. The second chapter treats both the communications to other planets in space vehicles and to a satellite repeater, repeating signals back to the earth. The basic problems of the communications, the recent advances and the requirements of space systems are discussed in some detail. Typical systems are presented in terms of information bandwidth, transmitter power, antenna directivities, and receiver sensitivity. The third chapter treats power sources in the light of the space environment and the requirements of space vehicles. It considers both primary power sources and conversion techniques which include electrochemical systems, turbogenerators, magnetohydrodynamic conversion, thermocouples, thermionic conversion devices, quantum conversion techniques, (solar cells), and fission-electric conversions. Present state-of-the-art capabilities are outlined in some detail. In the fourth chapter many problems of the man in a space capsule are treated, including that of the closed life cycle. Specific methods of sustaining life in a space cabin are suggested and experiments are described. In "Radiation and Man in Space" an introduction is given on the effect of radiation upon human tissue. Then, the types and intensity of radiation near the earth and in space are treated in some detail. In the chapter "Nutrition in Space Flight" all problems of nutrition are treated from the standpoint of the closed cycle cabin system. Human needs for nutrition and human wastes are described, together with experiments which have been conducted in this field. In the Appendix, the classification adopted by the International Astronautical Federation is given under 90 General Headings and 900 Detailed Headings.

Our Sun, by Donald H. Menzel

Published (1959) by Harvard University Press, Cambridge 38, Mass. 340 pages+10 index pages. 201 figures. $6\frac{1}{2}\times9\frac{3}{4}$. $7.50.

This is the second and revised edition of the Harvard Astronomy Series book on the sun. The first edition appeared ten years ago. The text and illustrations are for the most part unchanged, although there are numerous revisions, modifications, and additions. In fact, there are twenty-three additional illustrations bringing the total to over 200. These include many recent photographs and spectra of the sun.

The author is now the Director of the Harvard Observatory and is widely known and respected for his outstanding theoretical contributions to astrophysics and for the impact that he has had on solar astronomy in this country.

The text is easy to read and can be understood throughout by an undergraduate student of engineering; it can be read with profit by any engineer interested in the scientific aspects of the sun. Nearly every aspect of solar observation is included: the early history of solar observations, the basic elements of chemistry, physics, spectroscopy, radio observations, ionospheric measurements, and atomic energy. The text concentrated principally on the description of the physical characteristics of the sun such as rotation, energy generation, sunspots, faculae, prominences, granules, flares, formation of solar absorption and emission lines, limb darkening, reversing layer, chromosphere, corona, spicules, solar magnetic fields, the relationship of solar activity to geomagnetic storms, auroras, solar cosmic rays, terrestrial weather, the uses of solar energy, and the relationship of the sun to the stars.

The instruments of optical observations and the techniques of solar measurements are simply described. The details of about 200 solar eclipses occurring in the twentieth century are given in groups according to each individual saros epoch. This is an interesting table to study in order to acquaint oneself with the patterns of solar eclipses.

This book is not a treatise, it does not use mathematics and there are no references to the literature. A large number of solar astronomers are mentioned, but the choice clearly reflects the author's personal approach. For example, Barbara Bell, a colleague, is referred to as often as are Professors Unsold and Minnaert combined.

Solar radio astronomy is sketchily presented and the material given doesn't properly represent the amount of effort in this field. No mention is made of the exciting work going on in Paris and Tokyo, for example.

This is an excellent introductory book on the sun for the engineer. It is lucidly written and well illustrated.

Digital and Sampled-Data Control Systems, by Julius T. Tou

Published (1959) by McGraw-Hill Book Co., Inc., 330 W. 42 St., N. Y. 36, N. Y. 587 pages+7 index pages+11 bibliography pages+25 appendix pages. Illus. $6\frac{1}{4}\times9\frac{1}{4}$. $15.00.

In the field of sampled-data control systems a great amount of literature has appeared, but only a very few books have been published. This book takes its place along with the others as a notable contribution in bringing together the appropriate information. It is an excellent book.

The most notable features of this book are the logical development of the material, the manner in which various problems are faced up to, and the ease with which many of the topics are presented. The material reaches quite a bit beyond the theoretical and analytical aspects of sampled-data systems and touches on many of the practical problems such as quantization, analog-digital conversion, and specific circuit design considerations. In this respect one might ask why digital computer equipment and design was by-passed, but one readily visualizes the limitations on length of an already large volume.

In presenting the material the author assumes a strong reader background in control systems and servomechanisms. As a refresher, Chapter 2 summarizes this background material; but in an effort to condense, this chapter suffers from lack of clarity in places. The root-locus method for continuous data systems is probably the best part of this background material.

In dealing with sampling the author does not always distinguish between pulse and impulse modulations (*e.g.*, in the table of z-transforms, an impulse remains an impulse after impulse modulation), but here one can blame the negligence prevalent throughout the literature. What is nice in the exposition of both the methods and theories is the logical sequence in which problems are brought up and in the methods presented for their solutions. Somewhat too much emphasis is placed on Nyquist plots and their role in sampled-data analysis, but the use of root-locus and Bode plots is nicely stressed to balance the prevalent approaches in the literature. The theory of z-transformation is handled quite thoroughly and with considerable insight. System design, error analysis, and the use of error coefficients are treated. Statistical methods are used in several places and developed to at least a moderate extent.

The book shines not so much by its originality, but by the balanced bringing together of a wide variety of relevant methodology in a logical fashion. The amount of material presented is great, and the details are more often clarifying than cumbersome. It is clear that the author made a critical examination of the relevance and usefulness of the various methods, and in this reviewer's opinion he has exercised sound judgment in gaging their place and importance.

Encyclopedic Dictionary of Electronics and Nuclear Engineering, R. I. Sarbacher, Ed.

Published (1959) by Prentice-Hall, Inc., 70 Fifth Ave., N. Y. 11, N. Y. 1417 pages+x pages. Illus. $7\frac{1}{4}\times10\frac{1}{4}$. $35.00.

This book is truly an encyclopedic work, embracing, as it does the electronic and nucleonic fields. It obviously represents a thorough scanning of the definitions promulgated by the leading military and professional sources and includes over 14,000 terms.

The dictionary has been written for engineers primarily, and particular effort has gone into the nuclear portion in an attempt to clarify nucleonic terms for the electronics engineer who wishes to enter this new field. Thus the reader will find many of the nuclear items expanded, with considerable explanatory matter.

There are profuse illustrations, including many drawings of various types of reactors, and typical schematic diagrams for various electronic circuits, also drawings illustrating construction of many common electronic components.

This reviewer has made a spot check of the material in several fields and is of the opinion that there is a wide variation in timeliness in these fields. In addition, this work suffers from the same fault that occurs so frequently where an author chooses to paraphrase existing standards. In many places the text gives credit to the IRE for a particular definition, yet there are various changes in the wording of the existing IRE Standard. While the basic meaning may not have been altered, the author has lost sight of the fact that these are no longer official IRE Standards and thus have no official authority.

The reviewer must also take exception to the statement on the dust cover "This is the ONLY single source to provide you with *all* the standard definitions approved by official technical societies." In view of the liberties taken with a large percentage of the IRE definitions checked this statement is obviously misleading.

To comment on specific sections: The nuclear portion was drawn previously from the ASME Glossary of Terms in Nuclear Science and Technology, interspersed with some IRE definitions (some altered) and others. Unfortunately, the above-mentioned Glossary is not widely accepted and was issued as a preliminary standard, pending a more definitive effort which is currently under way in the ASA. Thus this dictionary perpetuates a number of terms which are obviously inadequate. As an example, the various definitions of *Plateau* and related terms are restricted to Geiger counters, whereas in the IRE Standards these definitions apply to Radiation Counter Tubes, a much more inclusive category.

Some liberties have been taken with standard ASA and IRE symbology, *e.g.*, T is occasionally used for time, which should be designated by t, T being used for temperature.

In the semiconductor field, the book leaves much to be desired. There are numerous errors, *e.g.*, a diode is defined as "a two-electrode electron tube," although examples of semiconductor diodes are listed; in the definition of *diffusion length* the term *majority carriers* should be *minority carriers*. The transistor material is about five years out of date, all the equations being given in terms of the T-equivalent circuit, whereas today's texts and specification sheets use the hybrid h parameters almost exclusively.

Finally, the reviewer noted this amazing statement: "Standardization of transistor schematic symbols for point contact and junction transistors has not been attained." The text then proceeds to use both graphical and letter symbols at variance with the standardized IRE forms. The writer would have been better informed if he had consulted the IRE in this respect, as these items have been standardized since 1956 and 1957.

Despite these glaring errors, the book is still an important contribution to the art, provided the reader bears one thing firmly in mind: it is a dictionary, a glossary, definitely *not* a compendium of standard definitions, hence cannot be quoted or used with any official exactness. The reader who wants complete rigor in his definitions must refer to the official works of the respective technical societies. This particular society, the IRE, cannot give official sanction to the definitions ascribed to it, for the obvious reasons illustrated above.

Radar Meteorology, by Louis J. Batten

Published (1959) by The University of Chicago Press, Chicago 37, Ill. 154 pages+7 index pages+xi pages. Illus. $6\frac{1}{4}\times9\frac{1}{2}$. $6.00.

This book will serve to acquaint the radar designer with the pertinent characteristics of weather which effect the propagation of microwave energy through the atmosphere. Also, meteorologists who desire to know more about the use of radar as a meteorological tool will find this book useful. There is a wealth of references throughout the book, which enhances its usefulness to those doing research as well as to the radar designer and the synoptic meteorologist. The author states in the preface that his purpose is one of . . . "briefly describing in one small volume the progress made since the birth of radar meteorology" This he has done in a well organized manner.

The book starts with a short chapter on some of the basic principles of radar, apparently directed at the meteorologist. The following five chapters are devoted to a more detailed consideration of the properties and propagation of electromagnetic waves, the use of the radar equation for determining power returned from reflecting spherical particles, scattering from nonspherical particles and factors which influence the attenuation of electromagnetic waves.

Chapter seven covers the use of radar as a means of providing quantitative measurements of precipitation. Following this is a short discussion of the types of distortions which are to be expected as a result of having finite pulse lengths and beamwidths. The effects of antenna sidelobes are also mentioned.

With chapter nine the book begins to devote more to the meteorological aspects of "Radar Meteorology." It briefly describes mechanical, photographic and electronic methods of integration used in conjunction with rain gauges for determining the amount of rain falling over an area. The next chapter is concerned with the use of radar for cloud physics research. It covers such items as detection of precipitation in, and growth of, convective clouds, diameter and duration of convective echoes, the "bright band" phenomenon, precipitation generating levels and the use of radar for assessing results of cloud seeding.

The use of radar as a means of obtaining otherwise unavailable information on thunderstorms, squall lines and tornadoes is discussed in some detail in chapter eleven. This is followed by a discussion of the use of airborne radar in aircraft operations as an aid toward reducing flight hazards.

In recent years radar has proved to be valuable in the study and prediction of the behavior of hurricanes and other large weather systems. A discussion of the information obtained by radar from such weather phenomenon is covered in chapter thirteen. This is followed by a short chapter on radar echoes (angels) which may occur during the absence of precipitation. The book concludes with a description of special techniques, such as isoecho contouring and stepped grey scale, which may be used in conjunction with the existing radar circuits to enhance the usefulness of the radar set as a meteorological device.

While this is not a profound book, it will serve to acquaint the uninitiated with the possible uses of radar for meteorological purposes. The author has done an excellent job of providing references to books and papers that are pertinent to the subject of Radar Meteorology.

Scanning the Transactions

Single-sideband goes underwater. SSB enthusiasts may be be interested to know that single-sideband suppressed-carrier transmission has proved to be the only effective system for underwater communication. FM is entirely unsuited to transmitting acoustic energy through water because phase disturbance of the wave components becomes so great that the essential characteristics of the signal are completely destroyed. Conventional AM is subject to undesirable fluctuations in the signal due principally to the presence of the carrier. Suppressed-carrier SSB has provided the most satisfactory answer. A mobile system recently designed for use between a hovering helicopter and a submarine had the following rather typical performance characteristics: a carrier frequency of 8 kc, modulation frequency of 200 to 3000 cps, transmitted power of 20 watts, and a range of 5,000 to 10,000 yards. An interesting feature of the receiver, one which simplified the design and minimized the problem of signal drift, was the use of a double heterodyning system for recovering the signal in place of the usual process of generating and reinserting the carrier into the incoming suppressed-carrier signal. (N. D. Miller, "An underwater communication system," IRE TRANS. ON COMMUNICATIONS SYSTEMS, December, 1959.)

A new look in phonograph needles may be in the offing. While the change may not be detectable to the eye, it will be to the ear. The tips of present day needles are in the shape of a hemisphere having a radius of 0.5 to 1.0 mil. Unfortunately this shape, while convenient to fabricate, does not correspond to the shape of the stylus used to cut records. This difference causes tracing distortion during playback, an effect which can be reduced by decreasing the radius of the needle tip, but only at the expense of increasing the wear and tear on the record. The new needle being proposed is in the shape of a pyramid, closely resembling the shape of the cutting stylus. This new shape, while more costly to produce, results in less distortion and background noise and longer life for recordings, both monaural and stereophonic. (C. D. O'Neal, "The pyramid stylus," IRE TRANS. ON AUDIO, November-December, 1959.)

Ultrasonic welding celebrates its tenth birthday this year. It is still a poorly understood process, although ultrasonic welders have been successfully designed by trial and error methods for limited applications. Until the basic principles of the process are better known, however, the development of equipment will continue to be empirical and the limitations of the process will remain unknown. What is believed to be the first fundamental study of the mechanisms involved in ultrasonic welding has now been reported. It appears that the welding process, in which surfaces subjected to a clamping action are welded when made to slide in contact with each other, is directly related to the well-known frictional phenomena of galling and seizing. This study also disclosed how clamping force, duration of weld cycle, ultrasonic motion, and temperature are related to weld strength. Present indications are that practical ultrasonic butt, seam, and spot welders can be designed for welding thin-gauge sheets or small components of ductile materials. (J. N. Antonevich, "Ultrasonic welding equipment," IRE TRANS. ON ULTRASONICS ENGINEERING, February, 1960).

Choosing the best type of communication system for a particular application is neither a purely technical problem nor a purely economic one, but a complex combination of these two factors. One engineer with considerable experience in this field has devised a novel formula for rating one system against another which takes both factors into account. This rating formula provides a good first-order approximation of the relative merits of various systems, making it possible to narrow down the number of systems that must be analyzed in greater detail. The formula for system performance rating is given by

$$\text{SPR} = \frac{\text{number of repeaters} \times \text{error rate}}{10^3 \times \text{available bandwidth (mc)} \times \text{availability}} \times \log_{10} (\text{TPR} \times \text{RPR} \times 10^7),$$

where TPR (transmitter power rating) is equal to transmitter power × antenna gain/bandwidth (cps); RPR (receiver performance rating) is equal to receiver antenna gain/[receiver noise figure] × [bandwidth (cps)]; and "availability" is the fraction of the time that the transmission medium is available for use. The lower the system performance rating is, the more desirable it is, *i.e.*, the lower the cost is. It will be interesting to see how well this evaluation technique, which thus far has checked out well, stands the test of time and experience. (J. H. Vogelman, "Comparative evaluation of communications transmission media," IRE TRANS. ON COMMUNICATIONS SYSTEMS, December, 1959.)

The radiation tolerance of electronic components is receiving a growing amount of attention in the design of equipment for both civilian and military applications. A number of organizations have been exploring the effects of radiation on standard components for the past several years. The results of these investigations, reported in over 600 scattered documents, have now been compiled in a single information file. By means of this file it has been found possible to modify existing equipment by selective replacement of radiation-sensitive parts with standard parts having a higher radiation tolerance. With this approach, circuits remain essentially unchanged, yet the amount of radiation the equipment can withstand has been raised orders of magnitude. Thus while more radiation data is still needed, it appears we have now reached the point where radiant-tolerant equipment can be successfully built with what is presently known, without need for extensive radiation testing. (J. R. Burnett, "Radiation-tolerant electronic equipment," IRE TRANS. ON NUCLEAR SCIENCE, December, 1959.)

The development of new low-noise amplifiers has changed the emphasis in communication system design from considerations of receiver noise to considerations of external noise. The noise level of a maser can be as little as one-thousandth that of a conventional amplifier. The question arises how much of this improvement is actually realized in an operating system and how much is lost to external noise. The answer has now been worked out at least for one type of system—a tropospheric scatter system operating in the 1000 to 2000 mc range. It has been found that the cooled-crystal technique will provide a system improvement of 3 db, the parametric amplifier 9.5 db, and the maser 12 db. When the problems associated with liquid helium operation of masers are taken into account, it appears that the parametric amplifier is the best choice. (A. Feiner and D. Savage, "The effects of low-noise techniques on tropospheric scatter communications," IRE TRANS ON COMMUNICATIONS SYSTEMS, December, 1959.)

Abstracts of IRE Transactions

The following issues of TRANSACTIONS have recently been published, and are now available from the Institute of Radio Engineers, Inc., 1 East 79th Street, New York 21, N. Y. at the following prices. The contents of each issue and, where available, abstracts of technical papers are given below.

Aeronautical and Navigational Electronics

Vol. ANE-6, No. 4, December, 1959

Frontispiece (p. 210)

Airborne Dual Antenna System for Aerial Navigation—W. Spanos and J. M. Ashbrook (p. 211)

This paper describes a 1000-mc dual antenna system which uses parallel-driven sector antennas. Methods for determining the performance in pattern interference regions are given together with applications to DME, Radar Safety Beacon and TACAN navigation systems. A flyable-model dual antenna system for Constellation and DC-6 type aircraft is described. Provision of an RF hybrid permits the simultaneous operation of two navigation equipments, such as DME and Radar Safety Beacon, from the same antenna system. A prototype of this antenna system on a DC-3 has provided improved performance for the TACAN navigation system. Flight tests with an experimental dual antenna system have shown improved performance for DME and Radar Safety Beacon systems. The results of flight tests show agreement with theoretically determined values of performance.

The Indeterminacy of Measurements Performed by Radar Equipment—R. Madden (p. 219)

A theoretical derivation of the indeterminacies of simultaneous position and velocity measurements of a reflector when using reflected electromagnetic waves is given. It is shown that the product of the indeterminacies is given by $1/(8\pi)/\lambda_S c$ where λ_S is the illuminating wavelength and c the speed of light. It is shown that the necessary consequence of nonsimultaneous measurements is an uncertainty as to whether the measurements are common to the same reflector. If this uncertainty is to be overcome, the reflectors must be spaced at a distance $\frac{1}{2}c\Delta T$ where ΔT is the time separation of the position and velocity measurement.

Principles of Electronic Navigation Systems—P. C. Sandretto (p. 221)

Electronic navigation systems of all types are discussed, and classified as classical or self-contained. The error rates and accuracies of the various systems are discussed.

Anticipatory Display Design Through the Use of an Analog Computer—L. J. Fogel and M. Dwonczyk (p. 228)

Modern high-performance aircraft currently are pressing the limitations of the human operator. The increased speeds compress the allowable reaction time to such levels wherein logical decisions, and even conditioned reflex actions, may no longer be possible. The only way to overcome this human limitation of manned aircraft performance is through the incorporation of anticipatory displays; displays which offer a prediction of the various parameters so that the human operator is projected ahead of the system. An aircraft was analog computer simulated, data reduction was programmed and the same computer was used to allow biophysical measurement, which furnished correlative measure. The effectiveness of various piloting techniques, as well as prediction intervals, was explored. The results indicated a first approximation to the design of improved displays through the use of anticipatory information.

The Pyramid Stylus—C. D. O'Neal (p. 140)

A new shape for a phonograph needle stylus is described which greatly improves the reproduction possibilities from phonograph records. The new stylus was specifically produced for use with 45°–45° stereo recordings, but will perform equally well on all microgrooved monaural recordings. The scheme described evolves a shape of reproducing stylus having a basic geometry relating to the cutting stylus used in forming all microgrooves. Computations, experimental data and charts are also used to support the improvements to be expected in reproducing reproduction performance.

Time-Frequency Scanning in Narrow-Band Speech Transmission—D. L. Subrahmanyam and G. E. Peterson (p. 148)

Two basic sampling methods for the transmission of intelligible speech with reduced channel capacity have previously been studied. The channel vocoder developed by Dudley is based on frequency band separation or quantization, and Schisser, and Fairbanks, Everitt, and Jaeger have developed a technique of time sampling. Sampling in both time and frequency offers a third major possibility which should be investigated.

For this study a narrow-band speech transmission system was constructed which scans the time-frequency plane. The system scans in either a sinusoidal or in a sawtooth manner over a frequency range of 200 to 7000 cps. In order to achieve the scanning, a variable carrier frequency oscillator, having a frequency shift of ±30 per cent of the carrier frequency and an amplitude modulation of ±2 db, has been developed. The process of scanning leaves empty spaces in the time-frequency plane, and a four-channel time-delay system which employs the method of dielectric recording has been used to fill the gaps in the time-frequency plane by repeating the signal samples.

When signal reiteration is employed with this system, a score of 75 per cent of monosyllabic phonetically balanced word lists was obtained with a scanning filter of 1000-cps bandwidth and a sinusoidal scanning rate of 30 times per second. This intelligibility is appreciably higher than that which can be achieved with a fixed 1000-cycle filter located in the frequency region of maximum intelligibility.

Circuits for Three-Channel Stereophonic Playback Derived from Two Sound Tracks—Paul W. Klipsch (p. 161)

Derivation of a third playback channel from two stereo sound tracks may be accomplished by several means. The center channel may be derived by recombination prior to power amplification; acoustically, after amplification, by using two center speakers; and in a variety of phase relationships, including the limiting case of equal signals (monophonic) in which either sum or difference combination may be chosen by polarity selection.

Characteristics of Degenerative Amplifiers Having a Base-Emitter Shunt Impedance—William D. Roehr (p. 165)

In amplifiers having emitter degeneration, an impedance is sometimes used between base and emitter. A common case occurs when several emitter followers are used in cascade. The resistors become necessary in order to provide some measure of stability.

In an audio amplifier of similar design it became necessary to know what effect this shunt resistor would have upon the input impedance of the stage. As a result, the analysis given in this paper was performed. Experimental measurements which support the resulting equation are given.

This analysis and these measurements led to the discovery of a circuit which would exhibit a high ac input impedance, yet the resistors in the dc base circuit could be kept low to provide good stability. Although it can be shown that circuit power gain is the same regardless of whether a resistor is used in series with the emitter or the base to obtain a high input impedance, considerations of dc stability and distortion demand a more thorough investigation of this problem.

Design principles are outlined for this high input impedance stage and an example is worked out in detail. Supporting measurements are given.

Communications Systems

Vol. CS-7, No. 4, December, 1959

Frontispiece and Guest Editorial (p. 227)

Comparative Evaluation of Communications Transmission Media—Joseph H. Vogelman (p. 230)

The selection of communications transmission media for any specified operation is neither a purely technical problem nor a purely economic one, but a complex combination of these two factors. To minimize work involved in evaluating all the possible choices, a first-order approximation method is provided to limit the number of specific transmission media which must be considered in any specific application. This method provides a numerical measure of the expected combination of technical and economic factors and is based on the author's empirically-derived experience with communications equipments and systems.

Design Considerations for Space Communication—J. E. Bartow, *et al.* (p. 232)

With the advent of Russian and American artificial earth satellites, the use of such vehicles for communication purposes has been the subject of considerable study both by military and commercial organizations in the communications field. The purpose of this paper is to delineate the problems involved in space communication, the assumptions that must be made and the technical limitations which determine the communication system that should be used for a particular time frame. Some characteristics for an optimum system are stated. Some technical characteristics of the first successful satellite communication system are given.

Development Trends in USAF Global Communication Systems—C. A. Strom, Jr. and A. A. Kunze (p. 241)

This paper briefly summarizes one initial development approach for the 1962–1965 USAF Global Communications Systems. A brief review is given of some of the early communications systems work and the present design philosophy for the 600-voice bandwidth channel, 6000-mile trunk system is discussed. Specific requirements of the ground-based Air Force common-user system are listed and developments intended to provide much of the equipment for this time period are noted. This paper concludes that by adopting the system approach, the Air Force will be provided with a greatly increased communications capability at a total cost which differs little from today's annual expenditure.

An Underwater Communication System—Norman D. Miller (p. 249)

Communications between submerged submarines and surface craft require energy to be propagated through sea water. The only practical method for transmitting this energy is by acoustic means. Both FM and AM transmission systems have been used, but for long-range communication, a single-sideband suppressed-carrier transmission system is the only effective way of propagating sound energy. The requirements for the transmission system and diagrams of the circuitry are given.

Wide-Band Facsimile Transmission Over a 900-Mile Path Utilizing Meteor Ionization—W. H. Bliss, *et al.* (p. 252)

Preliminary tests of facsimile transmission over a 910-mile path have been made at 40 mc by means of intermittent meteor ionization. Printed matter was scanned at a rate of 2 frames per second, with a resolution of 67 elements per inch. An all-electronic facsimile system recorded a picture when the received signal rose above a preset threshold.

Tests were conducted employing bandwidths up to 110 kc with keying frequencies up to 73 kc, still maintaining the same optical resolution in the facsimile material. With the equipment used in the tests, it appeared that the maximum bit rate for acceptable facsimile was about 48,000 bits per second at 2 per cent duty cycle and about 86,000 bits per second at 1 per cent duty cycle. Examples of signal recordings with received facsimile are shown.

Preparations are being made to conduct similar tests, employing a higher information rate and wider bandwidth, on a frequency near 50 mc.

A Very High-Speed Facsimile Recorder—G. M. Stamps and H. C. Ressler (p. 257)

An operating facsimile system is described which is capable of transmitting black and white graphic information at the rate of 24 inches of copy feed per second. The system uses conventional line-by-line sequential scanning at the transmitter and a multistylus recorder with 100 lines per inch resolution at the receiver. The electrolytic recording medium employed is characterized by a relatively low internal impedance, which permits close spacing of the stylus electrodes and the use of direct-coupled transistors for the individual marking amplifiers. The high transmission speed results from the use of individual stylus electrodes for each elemental area along the scanning line and the holding of the video marking signal at each stylus for time intervals approximating the duration of a complete scanning line. The system described uses a 100-stylus block assembly, restricting the length of the scanning line to one inch. One thousand-stylus block assemblies have been made and these will permit reproduction of copy 10 inches wide.

The NBS Meteor Burst Communication System—R. J. Carpenter and G. R. Ochs (p. 263)

This project was undertaken in 1955 to investigate the properties of the intermittent reception of VHF signals over long distances by meteoric propagation and their communication usefulness. To accomplish this, a complete duplex teletype system operating at about 50 mc was constructed, and results are reported from tests made over a 1277-km east-west path. Comparisons are made of burst transmissions of 10, 20, 40, and 80 times normal teletype speed and of variations in a number of control system parameters.

For the system under test, the optimum speedup was 40×, which produced a daily average channel capacity of about 40 wpm with a character error rate of about 0.0035 (with the best control system settings). Higher speedup ratios are advocated for future systems. The most serious causes of outages in this type of system are atmospheric noise and sustained multipath distortion from competing modes such as E_s and auroral propagation.

White Alice System—Design and Performance—A. L. Durkee, *et al.* (p. 272)

White Alice is an extensive communications network covering the entire state of Alaska. It provides essential defense communications as well as service for other government agencies and civilian commercial service. Both telephone and telegraph channels are provided with capacity for future growth. The Western Electric Company, as prime contractor for the USAF AMC, undertook the engineering, procurement, and installation of the electronic equipment as well as construction of some of the sites.

The Bell Telephone Laboratories participated in the basic systems engineering and furnished consulting assistance in new scientific areas. New designs were made or supervised by the Laboratories. The White Alice system plan is based on the study by the Bell System of the communications needs of the area.

Radio transmission was chosen for the majority of the routes. Wire and cable were considered either unreliable or impractical in the Alaskan terrain and climate. Where several hundred voice channels were required, microwave line-of-sight radio was used. For the majority of the links, tropospheric beyond-horizon transmission was used because of the economy and simplification of maintenance and logistic problems.

The transmission objectives for the entire system were a median noise in the worst month of 38 dba and a maximum of 1 per cent outage in the worst month. These objectives were for 4000-mile circuits and were prorated to each link.

The microwave portions of the system were engineered in the same way that has been used previously. Tropospheric beyond-horizon was a relatively new mode of radio transmission and the engineering procedures were less well defined. Propagation experience from a year-long test in Newfoundland, in addition to research by other groups, was used as the basis for the system engineering. These data include variation of signal strength from day to day and seasonally, the effective gain of the large antennas employed, the characteristics of the rapid fading typical of tropospheric propagation, and the effects of geographical profile and separation of the stations.

Towards the completion of the project, comprehensive transmission tests were made of many of the links of the system to determine that the design objectives had been met. In particular, a 2400-mile circuit traversing much of the system was tested. The transmission stability and noise performance over a 30-day period was well within the limits set in the objectives. Teletype and voice performance were eminently satisfactory.

White Alice has been operating continuously since it was turned over to the Air Force in March, 1958. Its reliability has been gratifying to the military and other agencies using it. It is certain to be a significant factor in the development of this last frontier.

Installation and Operational Aspects of a Private Television Microwave System—Aaron Shelton (p. 278)

The problems of installation, operation and maintenance of a 165-mile, six-hop, private, intercity television relay system are reviewed. Careful planning of the path to be used is required. Equipment, its housing, power and frequency chosen for this service require careful evaluation. Emergency power supplies are required. Numerous modifications to commercial equipments were found necessary. The problems of sound diplexing through a multihop system proved difficult, but possible and worthwhile. Careful maintenance schedules and techniques developed for checking operation of each station proved their value. Communications for a multihop system become very important. Manpower required for a system of this magnitude proved to be greater than expected. Equipments designed and field checked for multihop installations can only be considered if truly dependable service is required and expected.

Practical Considerations in the Design of Minimum Bandwidth Digital Frequency Modulation Systems Using Gaussian Filtering—W. L. Glomb (p. 284)

The characteristics of a digital frequency modulation system are reviewed. The Gaussian frequency response is specified and optimum filters for transmitter and receiver (both predetection and postdetection) are developed. The relationship between peak deviation and system threshold is explored and an optimum deviation established. The location of the Gaussian filters in the system is discussed. It is shown that for best threshold performance, all receiver filtering should be predetection filtering and that optimum peak deviations under these conditions may correspond to the −4-db point of the IF filter. Practical details of transmitter and receiver design are discussed.

These results have been applied to a 2000-mc communication equipment.

A Study of the Technical and Economic Feasibility for Tropospheric Scatter Circuits in Primary Toll Networks of Underdeveloped Countries—C. A. Parry (p. 290)

The inherent capabilities of the tropospheric scatter circuit have emphasized the need for careful economic and technical evaluation. It is suggested that this should be carried out in two phases. The first is a broad study which determines the essential system parameters for which detailed analysis is necessary. The second phase is concerned with this detail. Outlines are given relevant to the principal factors associated with the first of these phases. These cover such areas as trunk circuit growth, required channel, capacity at the end of the amortization period, revenue potential, optimum routing, choice of transmission method, and the optimum number of tandem tropospheric scatter links. The performance sacrifice for a minimal cost "first in" system and the manner in which design accuracy may be traded against probable propagation reliability are two of the problems discussed. Evaluation of the scatter link may be based on a performance index and data relevant to this are given. It is concluded that adequate analysis of the modern system capability requires a sophisticated engineering approach for which the present paper is a guide.

50-kw Antenna Switching System—John W. Smith (p. 295)

There are many HF radio installations today that illustrate the need for an improved antenna switching technique. Today there is a growing requirement to connect rapidly any one of several 50-kw transmitters to any one of many antennas. An antenna switching system must be broad-band, convenient to use, fast, safe for operating personnel, and free of appreciable impedance discontinuities. This paper describes several components and techniques that solve the transmitter-antenna selection problem up to a 50-kw power level. The influence of switching techniques on RF transmission, impedance conversion and antennas are also discussed.

The Effects of Low-Noise Techniques on Tropospheric Scatter Communications—A. Feiner and D. Savage (p. 302)

This paper defines the expected benefits to be derived from the use of low-noise receiver techniques when applied to tropospheric scatter systems in the 1000- to 2000-mc range. Calculations were made of the expected antenna noise temperatures for "smooth" and "rough" ground locations. These data, plus the known and anticipated performance of various low-noise techniques, permitted the calculation of increased sensitivity. The sensitivity improvement is then expressed in terms of increased range, decreased transmitter power, and decreased antenna size.

Education

VOL. E-3, NO. 1, FEBRUARY, 1960

Editorial (p. 1)

The Research Flavor—John S. McNown (p. 2)

Research should be made a significant part of undergraduate engineering education in order to orient the student toward the solving of new problems. He should learn of the frontiers of his field of study, and should know of the people who are pushing back these frontiers.

An increase is needed in the number of courses designed for guiding a student to define problems, to make assumptions, to search for his own methods of solving them, and to develop a way to report his findings. Almost as a dividend, new ideas and the exercise of originality provide a strong motivation to learning.

The Scientific Manpower Shortage and Its Implications for the Engineering Technician—John Merrill (p. 3).

Some of the background of the present scientific manpower shortage is reviewed. Utilization as an important aspect of engineer efficiency is discussed. With this setting, the engineering technician's complementary function with the engineer is introduced. The limited availability of technicians is cited. A discussion of the *stepping-stone* aspect of the technician job, an area worth consideration because of its ramifications, is presented and the concept of a four-year program for engineering technicians is shown to have significant value in coping with several phases of technician training.

Four areas of study and investigation are suggested that can contribute to solution of the over-all need of increased scientific manpower through increased utilization. Utilization would be improved by the proper preparation of an adequate number of engineering technicians.

Circuit Analysis—A Problem in Semantics—Thomas M. Adams (p. 10)

The teaching-learning process in circuits is enormously complicated by the multiple meanings and shades of meanings which are inherent in most of the technical terms. A method is offered for reducing every term relating to "functions" to its basic meaning for the particular circuit application under study. Using this method, which might be called "current analysis," it becomes possible to explain detailed circuit phenomena to students with little or no technical or mathematical background.

A General Course in Traveling Waves—R. K. Moore (p. 15)

Traveling waves must be considered whenever the time for a disturbance to propagate from one place to another is important. A course with this as its theme has been developed to replace the usual course in transmission lines or distributed constant circuits. Emphasis is placed on the transmission line as a teaching vehicle, but plane waves in space; vibrating strings and membranes; acoustic waves in gases, liquids and solids; heat conduction; and chemica diffusion are also treated. The analogies between the "telegraphers' equations" and comparable equations describing nonelectrical phenomena are stressed.

Transients are treated for two special cases: 1) lossless lines and acoustics, and 2) diffusion and heat transfer. Steady state analysis using phasors and the Smith Chart is applied to plane electromagnetic and acoustic waves at all angles of incidence, as well as the transmission line. Spherical acoustic waves are treated briefly.

A First Course in Electrical Engineering—P. R. Clement and W. C. Johnson (p. 19)

This article describes the introductory two-semester course in electrical engineering that has been developed over a period of five years at Princeton University. The aims of the course are to provide an introduction to the field of electrical engineering via the basic concepts of electricity and magnetism (which are developed through Maxwell's equations in the integral form), to apply these concepts in developing the fundamentals of energy conversion and circuit theory, and to carry forward, in a continuous and integrated way, a modern treatment of network analysis. Thus, the treatment proceeds from field ideas to circuits and physical apparatus, and to their mathematical models. With the circuit relations formulated, attention turns to the analysis of networks, starting with network topology and extending through pole-zero ideas. The treatment stops just short of the Laplace transform. This course is intended to serve as a foundation for subsequent courses such as electronic circuits, energy conversion, and advanced network analysis and synthesis, and has been developed with the purpose of providing the student with a unifying point of view for these varied topics.

The Organization of a Laboratory Electronics Course—D. Blackwood (p. 22)

This paper describes the organization of a Laboratory Electronics Course in the Department of Aircraft Electrical Engineering at the College of Aeronautics, Cranfield, England. The course caters to two standards of specialization and to students with a wide range of previous training.

The minor specialization course concentrates solely on fundamentals and the basic concepts, while the major course is carried to the threshold of design procedures. The contents of both courses are limited to the student's previous training and the time available for practical work. The over-all standard of the major course is that of the M.Sc. degree of a British University.

Four different ways of construction and presentation of experiments are described and the limitations of each are discussed. Finally, the laboratory layout, equipment, and scheme of work for both courses is described.

A Supplementary DC Machine Test for Sophomores—E. Della Torre and C. V. Longo (p. 25)

A blocked-rotor test may be used to determine curves for a family of dynamic operating characteristics for dc machines. Conventional performance characteristics may be predicted from these curves. The authors have used this test procedure to supplement the usual tests on machinery in the sophomore laboratory. The new procedure emphasizes the fundamental principles of machine operation and also points up the importance of certain details which have a significant effect upon performance. The test would logically precede the usual load tests. The latter are then anticipated with enthusiasm since they provide confirmation of performance predicted from the static tests.

Information Theory

VOL. IT-5, NO. 4, DECEMBER, 1959

Frontispiece (p. 148)

Editorial (p. 149)

A Class of Systematic Codes for Non-Independent Errors—N. M. Abramson (p. 150)

A class of systematic codes has been obtained which will correct all single errors and all double errors which occur in adjacent digits. These codes use significantly fewer checking digits than codes which correct *all* double errors. In addition, because of inherent regularities in their structure, these codes may be instrumented in a strikingly simple fashion.

A Probabilistic Model for Run-Length Coding of Pictures—Jack Capon (p. 157)

A first-order Markoff process representation for pictures is proposed in order to study the picture coding system known as run-length coding (differential-coordinate encoding). A lower bound for the saving in channel capacity is calculated on the basis of this model, and is compared with the results obtained by previous investigators. In addition, this representation is shown to yield an insight into the run-length coding system which might not otherwise be obtained. The application of this probabilistic model to an "elastic" system of run-length coding is also discussed.

A Note on Invariant Relations for Ambiguity and Distance Functions—C. A. Stutt (p. 164)

Woodward's result for the ambiguity function, that the volume associated with its squared magnitude over the time-shift and frequency-shift plane is a constant, has been shown to be true also for a cross-ambiguity function for two time functions. If complex time functions have been obtained by means of a Hilbert transformation from real time functions, it is found for the cross-ambiguity function that the volumes under the squared real part and under the squared imaginary part are constant and contribute equally to the volume under the squared magnitude function. A "distance" function for two time functions is defined to be the integrated squared difference between these functions. The relation for the squared real part of the ambiguity function readily yields an invariant relation for the volume associated with this distance function in the case of Hilbert-derived complex time functions. An especially simple invariant relation for the "mean" distance, as computed over the time-shift and frequency-shift plane, exists for such time functions having finite energy and finite mean value.

On Upper Bounds for Error Detecting and Error Correcting Codes of Finite Length—Nelson Wax (p. 168)

Upper bounds for error detecting and error correcting codes are obtained in this paper. One upper bound is found by exploiting the geometrical model of coding introduced by

Hamming. The volume of an appropriate geometrical body is compared with the volume of the unit cube, in getting the first upper bound. An improvement on this upper bound can be found by introducing a mass density function, and comparing the mass of the body with the mass of the unit cube.

A comparison is made with known upper bounds, and with best codes found thus far. The improved upper bound given here is frequently somewhat smaller than previously known upper bounds.

The Probability Density of the Output of an RC Filter When the Input Is a Binary Random Process—H. A. McFadden (p. 174)

A new method is given for obtaining the probability density of the output of an RC filter when the input is a stationary binary random process. The axis-crossing intervals of the input are assumed to be statistically independent and identically distributed, but with an arbitrary density function. The method involves a linear integral equation which can be reduced by Laplace transforms. A new family of solutions is given which includes two previously known cases: the random square wave of Poisson type, and the periodic square wave with random time origin. The general result of this family is given in terms of tabulated functions. For other solutions, a recursive technique may be necessary.

Recurrent Events in a Bernoulli Sequence—M. B. Marcus (p. 179)

The "point of regeneration" method is used to obtain simple sequential equations for determining the complete probability density function for multiple occurrences of events in a Bernoulli sequence. Both the independent and overlapping classes of recurrent events are included in the general framework of these equations. The equations also lead to the generating function for the probability distribution. This is used to obtain the expected recurrent times for the different classes of recurrent events.

A distinction is made between the probability distributions for the occurrence of the kth event at the nth trial and the occurrence of k events in n trials. The latter case is of primary concern.

The methods employed and the results obtained have extensive applications in problems in automatic control, communications, and information processing.

Nuclear Science

Vol. NS-6, No. 4, December, 1959

Effects of Reactor Exposure on Boron-Lined and BF$_3$ Proportional Counters—William M. Trenholme (p. 1)

The results of reactor exposure on the characteristics of several types of boron-lined and BF$_3$-filled proportional counters are presented, and the important design and application criteria that lead to improved performance of counters after long reactor exposure are discussed.

The Describing Function of Nuclear Reactors—Henri B. Smets (p. 8)

The integro-differential equation of reactor dynamics is studied and approximated. It is found that a reactor can be represented by means of a linear system and a nonlinear system in cascade. The transfer function of the linear system is the classical low-power transfer function. The nonlinear system is a nonlinear amplifier with an exponential characteristic. The describing function is computed in the case of a water-moderated reactor and it is shown that gain near resonance increases with the magnitude of a reactivity sinusoidal oscillation.

Radiation-Tolerant Electronic Equipment—James R. Burnett (p. 12)

Transistor-Driven Beam Switching Tube Decade Counter—Richard H. Graham (p. 16)

This paper describes an electrical readout decade counter employing the magnetron beam switching tube with transistor drive. Double-pulse resolution is 1 μsec. The unit will accept a variety of transistor types, and will tolerate supply voltage variations of ±20 per cent at ambient temperatures up to 60°C. A "Pixie" neon indicator is driven without the use of additional transistors. A readout circuit for printer or punched paper tape is presented.

A Stack Effluent Radioisotope Monitor—R. A. Harvey (p. 20)

A system for simultaneously measuring and indicating each of several different radioisotopes in the stack effluent of an atomic energy facility is described. Analog computer techniques are employed for the solution of simultaneous equations and for the counting and scaling. Two types of presentations are included for the output. The total amounts of the radioisotopes emitted to the atmosphere are indicated on registers, and marks are recorded on a moving chart each time specific quantities are emitted. The emission quantity of each isotope is indicated by a register and by a single channel on the chart recorder.

Ultrasonics Engineering

Vol. 7, PGUE-8, February, 1960

Transducer Properties of Lead Titanite Zirconate Ceramics—D. Berlincourt, *et al.* (p. 1)

Physical properties of two commercial ceramics of the lead titanate zirconate family are presented and are compared with data for typical barium titanate ceramics. The importance of dielectric losses is stressed. Preference is given to showing heat generated as a function of nonresonant strain amplitude rather than electric-field amplitude. In this type of presentation, common barium titanate ceramics vary little from each other, while lead titanate zirconate ceramics are quite outstanding.

Thickness-Shear Mode BaTiO$_3$ Ceramic Transducers for Ultrasonic Delay Lines—John E. May, Jr. (p. 7)

The properties of thickness-shear mode BaTiO$_3$ ceramic transducers as applied to ultrasonic delay lines have been investigated. A method of fabricating these transducers has been developed which allows bonding to the delay line by conventional soldering techniques. Compared with thickness-extensional mode transducers, the shear mode transducers have a higher dielectric constant, a lower resistance and a lower capacitance ratio. Substitution for the former on short delay lines at 15 mc increased the bandwidth from 30 per cent to 43 per cent for the same loss. When the quartz transducers on the longer polygon-type lines were replaced with the ceramic transducers, the loss was reduced from 40 db to 20 db.

Vibrations of Ferroelectric Transducer Elements Loaded by Mass and Acoustic Radiation—F. Rosenthal and V. D. Mikuteit (p. 12)

The motion, stress distribution, and electrical impedance are calculated for idealized three-layer sonic transducers, consisting of a piezoelectric element loaded at either end by a mass which may be distributed or lumped, and loaded further by resistive plane-wave acoustic radiation. The piezoelectric element may be driven by use of either the d_{33} or d_{31} effect. The lumped constant equivalent circuit is given for the case of lumped end masses and negligible ceramic mass density. The lumped mass solutions are compared with the somewhat more realistic solution based on the assumption of distributed end masses (obtained on an IBM 650 computer).

Effect of Electrical and Mechanical Terminating Resistances on Loss and Bandwidth According to the Conventional Equivalent Circuit of a Piezoelectric Transducer—R. N. Thurston (p. 16)

This paper includes a rather complete analysis of transducer loss and bandwidth as a function of the mechanical and electrical terminations. For the case of tuning with a shunt coil, Fig. 1 shows lines of constant loss at midband and curves of constant bandwidth plotted with the electrical and mechanical terminations proportional to ordinate and abscissa, respectively. Besides enabling one to find quickly the loss and bandwidth corresponding to any pair of terminations and to visualize the effect of termination changes, this plot also reveals quickly the terminations which have special properties, such as zero loss at midband, zero minimum loss, widest band for a given loss, etc. The case of a series tuning inductor is treated by making use of an approximate correspondence with the shunt case. Results to be expected without a tuning inductor are also indicated.

Ultrasonic Welding Equipment—John N. Antonevich (p. 26)

Little or no work has been reported on investigations into the basic principles of ultrasonic welding. Until these principles are understood, the development of ultrasonic welding equipment will continue to be empirical and the limitations of the process will remain unknown. What is believed to be the first fundamental study of the mechanisms involved in ultrasonic welding has been started. On the basis of observations made in this study, it is postulated that this new welding process is a form of pressure or friction welding, in which material surfaces subjected to a clamping force are welded when made to slide in contact with each other. The process appears to be related directly to the frictional phenomena of galling and seizing.

The relationships between weld strength and the variables of clamping force, duration of weld cycle, ultrasonic motion, and temperature, have been obtained for a Monel sphere welded to a copper plate. This work shows that there is a minimum displacement and temperature required for welding. Also, that weld strength is directly proportional to clamping force, displacement, weld time, and temperature, up to critical values of these variables. Under conditions where critical values are exceeded, weld strength is decreased, apparently because of fatigue about the weld zone. The minimum displacement required for welding agrees with displacements calculated to be necessary to produce sliding.

The fundamental study shows that the essential components of an ultrasonic welder are: 1) an arrangement to clamp together members to be welded, 2) an arrangement to couple vibratory energy to one of the members being welded, 3) a controllable source of vibratory energy, and 4) a timing circuit to control the duration of clamping force and vibratory energy. On the basis of conditions found necessary to produce a weld, the problems encountered in designing welder components are discussed and methods of circumventing them are presented. To improve weldability of materials, welders could be developed to weld materials in vacuo or in an inert atmosphere. This would reduce oxidation around weld zones caused by frictional heating. A control circuit differentiating the temperature at or near the weld site could also be incorporated in ultrasonic welders to control the process and insure uniformity of strength of welds. Present indications are that practical ultrasonic butt, seam, and spot welders can be designed, but they would be limited in application to welding thin-gauge sheets or small components made of ductile materials.

ACOUSTICS AND AUDIO FREQUENCIES

534.2-8-14 722

Propagation of Finite-Amplitude Ultrasonic Waves in a Relaxing Medium—V. A. Krasil'nikov and D. V. Khaminov. (*Akust. Z.* vol. 5, no. 2, pp. 166–169; 1959.) Investigation of ultrasonic propagation at frequencies of 0.5, 1 and 2 mc in acetic acid at various concentrations.

534.2-8-14 723

Optical Investigations of the Waveform of Large-Amplitude Ultrasonic Waves in Liquids—V. A. Shutilov. (*Akust. Z.*, vol. 5, no. 2, pp. 231–240; 1959.)

A list of organizations which have available English translations of Russian journals in the electronics and allied fields appears at the end of the Abstracts and References section.

The Index to the Abstracts and References published in the PROC. IRE from February, 1959 through January, 1960 is published by the PROC. IRE, June, 1960, Part II. It is also published by *Electronic Technology* (incorporating *Wireless Engineer*, and *Electronic and Radio Engineer*), and included in the April, 1960 issue of that journal. Included with the Index is a selected list of journals scanned for abstracting with pulishers' addresses.

534.2-8-14 724

Propagation of an Acoustic Pulse in an Underwater Sound Channel—N. S. Ageeva (*Akust. Z.*, vol. 5, no. 2, pp. 146–150; 1959.) Investigation of the waveform of 3-ms ultrasonic pulses propagated over distances up to 20 km underwater. Recordings of these pulses are compared with ray diagrams corresponding to the experimental conditions. The pulse shape is observed to vary with the distance from the emitter.

534.213-8 725

Velocity and Attenuation of a Narrow-Band, High-Frequency Compressional Pulse in a Solid Waveguide—M. Redwood. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 442-448; April, 1959.) The Pochhammer-Chree solution does not correctly describe the propagation phenomena. A modification of the equations is proposed.

534.22-13 726

Velocity of Sound in Relaxing Gases—H. J. Wintle. (*Nature*, vol. 184, suppl. no. 26, pp. 2007–2008; December 26, 1959.) Measurements were made on pure CO$_2$, O$_2$ and dry air free from CO$_2$ of the velocity of sound and corresponding attenuation at frequencies in the range 100–1500 cps at a pressure of one atmosphere and a temperature of 30°C.

534.231 727

A New Method of Solving the Problem of a Sound Field in a Fluid Wedge—V. K. Kuznetsov. (*Akust. Z.*, vol. 5, no. 2, pp. 170–175; 1959.) Results are examined for the case of absolutely reflecting boundaries of the wedge. The theory indicates a new phenomenon of normal-wave refraction in the wedge with application to hydroacoustic shore refractions.

534.232-8 728

Dependence of the Gain of an Acoustic Focusing System on Sound Intensity—K. A. Naugol'nykh and E. V. Romanenko. (*Akust. Z.*, vol. 5, no. 2, pp. 191–195; 1959.) An expression is obtained for estimating the effects of nonlinear distortion in a focusing system on the amplification coefficient. Miniature receivers are used in investigating the waveform near the focus and the amplification coefficients of three BaTiO$_3$ focusing radiators operating at 0.5, 1.4, and 2.2 mc.

534.26 729

Diffraction of a Convergent Cylindrical Wave by a Cylinder—I. N. Kanevskiĭ. (*Akust. Z.*, vol. 5, no. 2, pp. 151–156; 1959.) A mathematical analysis of the diffraction of waves on an infinite cylinder disposed coaxially with the front of the wave. A comparison is made with the case of scatter of a plane wave on a cylinder of small circumference compared to the wavelength.

534.4 730

Theory and Practice of Vibration Analysis in the Transient Regime—L. Pimonow. (*Ann. Telecommun.*, vol. 13, pp. 100-111 and 125–152; March/April and May/June, 1958.) An analyzer based on the physical characteristics of the ear is evolved.

534.612:621.352:541.135.6 731

Analysis of a Logarithmic Solion Acoustic Pressure Detector—A. F. Wittenborn. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 475–478; April, 1959.) An approximate method is used which avoids solving the Navier-Stokes equation describing the fluid-flow and the convection diffusion equation for calculating the current.

534.75 732

Intensive Differential Thresholds for Octave-Band Noise—A. M. Small, Jr, W. E. Bacon, and J. L. Fozard. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 508–510; April, 1959.) Report of an experiment to determine the differential thresholds for octave bands of noise of different center frequencies at various sensation levels.

534.75 733

Multiple Observations of Signals in Noise—J. A. Swets, E. F. Shipley, M. J. McKey, and D. M. Green. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 514–521; April, 1959.) Information on the general properties of the hearing process is obtained from experiments on the gain in detectability resulting from repeated observations of a given signal in noise.

534.75:621.391 734

Indices of Signal Detectability Obtained with Various Psychophysical Procedures—Swets. (*See* 1013.)

534.76 735

Binaural Communication Systems: Preliminary Examination—I. Pollack. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 81–82; January, 1959.) Report of an exploratory study of a binaural system with rejection filtering in which selective operations are transferred to the listener.

534.76 736

On the Localization of the Apparent Sound

Source in Two-Channel Stereophonic Transmission—V. S. Man'kovskiĭ. (*Akust. Z.*, vol. 5, no. 2, pp. 176–182; 1959.) Stereophonic tests carried out at frequencies of 200, 1000 and 6000 cps in reverberation rooms of volume 1600 and 1500 meters^3 are described. The dependence of the apparent position of the sound source on the difference in sound level and the coordinates of the listener's position is investigated.

534.78 737

Intelligibility of Reiterated Speech—D. J. Sharf. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 423–427; April, 1959.) An attempt is made to increase the intelligibility of speech sampled in time (interrupted speech) by filling in the blank spaces with repetitions of the speech samples (reiterated speech). There appears to be little advantage in the technique.

534.78:621.391 738

Communication Efficiency of Vocoders—Billings. (*See* 1014.)

534.782 739

An Experimental Transistorized Artificial Larynx—H. L. Barney, F. E. Haworth, and H. K. Dunn. (*Bell. Syst. Tech. J.*, vol. 38, pp. 1337–1356; November, 1959.) A modified telephone receiver driven by a transistor relaxation oscillator, and powered by 10.4-volt Hg cells, is used to produce 0.5-msec pulses at the required pitch. The pitch can be changed and, in use, the telephone receiver is held against the throat.

534.79 740

The Relation between Loudness and the Sound Pressure on the Tympanic Membrane—G. Jahn. (*Hochfrequenz.*, vol. 67, pp. 69–72; November, 1958.) Subjective tests with specially developed equipment show that a given sound pressure at the membrane always results in the same loudness sensation irrespective of the shape of the external sound field.

534.845.1 741

Investigations on the Measurement of the Sound Absorption Coefficient in Echo Chambers—E. Steffen. (*Hochfrequenz.*, vol. 67, pp. 73–77; November, 1958.) The effect of the arrangement and shape of the absorbent material under test on the relation between measured and true absorption coefficients is investigated.

534.861:621.395.665.1 742

Contribution on the Reciprocal Control of Dynamic Range—Völz (*See* 1019.)

534.88 743

On the Detection of Signals in Nonstationary Noise by Product Arrays—J. B. Thomas and T. R. Williams. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 453–462; April, 1959.) Two detection systems having multiple inputs each consisting of nonstationary noise and a stationary random signal are analyzed and compared on the basis of signal/noise ratio.

534.88 744

Correlation of a Finite-Distance Point Source—M. J. Jacobson. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 448–453; April, 1959.) Errors in predicted source directions obtained with a two-receiver steerable correlation system are considered in relation to source distance.

534.88:621.396.965.4 745

Underwater Echo-Ranging with Electronic Sector Scanning: Sea Trials on R.R.S. Discovery II—D. G. Tucker, V. G. Welsby, L. Kay, M. J. Tucker, A. R. Stubbs, and J. G. Henderson. (*J. Brit. IRE*, vol. 19, pp. 681–696; November, 1959.) The general performance of the equipment and its ability to detect fish shoals is described, together with an account of the equipment design. See 3676 of 1958 (Tusher, *et al.*).

621.395.61.089.6:534.6–8 746

Absolute Calibration of Pitot Tubes and Microphones by means of Ultrasonics—V. Gavreau and A. Calaora. (*Ann. Télécommun.*, vol. 13, pp. 153–158; May/June, 1958.) A phase-difference technique for measuring the velocity of air flow is applied to the calibration of pitot tubes at low velocities. The technique is also applied to the absolute calibration of microphones at frequencies below 400 cps.

621.395.623.7:621.318.2 747

Loudspeaker Magnet Design—A. E. Falkus. (*Wireless World*, vol. 66, pp. 41–44; January, 1960.) Magnet design using capped cylindrical slugs of Alcomax III is described.

ANTENNAS AND TRANSMISSION LINES

621.372.2 748

Reflection Coefficients—R. A. Waldron and J. K. Skwirzynski. (*Electronic Radio Eng.*, vol. 36, pp. 464–465; December, 1959.) "The reflection and transmission coefficients are considered for reflecting surfaces which have the same medium on either side. It is shown that the reflection coefficient can be written cos $\theta \cdot e^{j\theta}$ and the transmission coefficient sin $\theta \cdot e^{j(\theta-\pi/2)}$, θ taking values between $-\pi/2$ and $+\pi/2$."

621.372.2.012.11 749

The Smith Chart—R. A. Hickson. (*Wireless World*, vol. 66, pp. 2–9 and pp. 82–85; January and February, 1960.) Derivation and uses of the chart are described.

621.372.2.09 750

Group Velocity and Energy Velocity of Electromagnetic Waves in Loss-Free Lines—W. Kleen and K. Pöschl. (*Arch. elekt. Übertragung*, vol. 12, pp. 567–569; December, 1958.) Energy velocity equals group velocity in two special models of loss-free delay line and in loss-free lines, in general, including those of periodic structure. This is not in agreement with the findings of Borgnis (696 of 1959).

621.372.8:621.77 751

Waveguide Bending Design Analysis—F. J. Fuchs, Jr. (*Bell Syst. Tech. J.*, vol. 38, pp. 1457–1484; November, 1959.) "The art of rectangular tube bending is analyzed, with particular attention being given to tube wall thickness variations. Effects of these variations on tool design are discussed and methods and formulas for determination of wall distortions are presented."

621.372.8.049.7 752

High-Pressure Microwave Window—A. W. Lawson and G. E. Smith. (*Rev. sci. Instr.*, vol. 30, pp. 989–991; November, 1959.) Two conically tapered single crystals of Al_2O_3, with small ends abutting, are used to effect simultaneously a high-pressure seal and a matched transformation from a standard 1-cm circular waveguide at atmospheric pressure to a circular waveguide terminated by a high-Q cavity resonator with an internal hydrostatic pressure up to 10^4 bars.

621.372.81 753

The Impedance Concept in Waveguide Theory—A. Guerbilsky. (*Ann. Télécommun.*, vol. 13, pp. 114–120; May/June, 1958.) Wave propagation studies are simplified by breaking down the propagated wave into uniform plane waves. The method is applied to a parallel-plate and a rectangular waveguide, each containing two dielectrics.

621.372.825 754

Ridge Waveguide Impedance—G. Duckworth. (PROC. IRE, vol. 47, p. 2121; December, 1959.) A simpler formula than that given by Mihran (2425 of 1949) is derived for the characteristic impedance.

621.372.831 755

Mode Conversion—L. Solymar. (*Electronic Radio Eng.*, vol. 36, pp. 461–463; December, 1959.) The electric intensities in the taper section and larger waveguide are determined, and the amplitudes of the spurious modes computed for the case of rectangular waveguides of different cross sections joined by a pyramidal tapered section. A simple formula relating the taper section length to the mode-conversion figure is derived.

621.372.831:621.317.373 756

Phase Measurements through Tapered Junctions—L. Lewin. (*Proc. IEE*, pt. B, vol. 106, pp. 495–496; September, 1959.) The electrical length of a tapered junction matched at the transitions to uniform waveguides is usually taken to be its physical length. A small correction, due to the cylindrical nature of the wave, is calculated theoretically.

621.372.852.22 757

Gyromagnetic Modes in Waveguide Partially Loaded with Ferrite—H. Seidel and R. C. Fletcher. (*Bell Syst. Tech. J.*, vol. 38, pp. 1427–1456; November, 1959.) Analysis is made of all the propagating modes of a vanishingly small rectangular waveguide partially filled with transversely magnetized ferrite. Each of these modes is shown to propagate in only one direction and to tend to be lossy. These properties are of use in the design of a nonresonance isolator.

621.372.855 758

Rectangular-Waveguide Loads—W. G. Voss. (*Electronic Tech.*, vol. 37, pp. 6–8; January, 1960.) Modifications to the construction and mounting of resistive-element dissipative strips when used either as fixed flat loads or as adjustable sliding terminations are described. The two loads are considered to be improvements on any previous design of low-power load, having particular application where a variation of voltage SWR is required over a wide range or where an extremely flat load is required.

621.396.67.095 759

Antenna Power Densities in the Fresnel Region—R. W. Bickmore and R. C. Hansen. (PROC. IRE, vol. 47, pp. 2119–2120; December, 1959.) Curves of maximum power density are presented as a function of distance from the antenna for typical aperture distributions.

621.396.677.43 760

The Horizontal Radiation Patterns of Rhombic Receiving Antennas for Short-Wave Transmission Paths—H. Bohnenstengel, W. Kronjäger, and K. Vogt. (*Nachrichtentech. Z.*, vol. 11, pp. 605–610; December, 1958.) Statistical methods were used to determine the horizontal radiation patterns of a rhombic with 115-meter sides at Eschborn receiving station, for frequencies 5, 10, 15 and 20 mc. Levels of side-lobe and backward radiation were also determined.

621.396.677.71 761

Pattern Synthesis for Slotted-Cylinder Antennas—J. R. Wait and J. Householder. (*J. Res. nat. Bur. Stand.*, vol. 63D, pp. 303–313; November/December, 1959.) Tchebycheff polynomials are used to calculate the distribution of excitation in phase and amplitude of the axial slots, arranged around the circumference of a vertical cylinder, which are necessary to produce the required beamwidth and side-lobe levels in the horizontal plane.

621.396.677.83 762

Passive Microwave Mirrors—R. G. Medhurst. (*Electronic Radio Eng.*, vol. 36, pp. 443–449; December, 1959.) Equations for the phase and amplitude of the near field, close to the main lobe axis, of the primary radiation are derived as modifications of the far-field expressions. Computation of the gain of the antenna-reflector system relative to the antenna alone is simplified; the results agree well with measurements and previously calculated results.

AUTOMATIC COMPUTERS

681.142 763

New Digital-Computer Techniques—(*Proc. IEE*, pt B, vol.106, pp. 444–469; September, 1959.) A report of specialist discussion meetings of the Measurement and Control Section of the IEE, February 16–17, 1959, dealing with character recognition, peripheral equipment, low-temperature storage and switching devices, and special aspects of logical design.

681.142 764

Study of Certain Errors in Analogue Computers—M. W. Overhoff. (*Ann. Télécommun.*, vol. 13, pp. 162–168; July/August, 1958.) Linear and nonlinear imperfections in adding and integrating circuits are related to errors in the solution of differential equations. Analog computers using only ac amplifiers are shown to be a practical proposition.

681.142 765

Electronic "Rotor"—J. S. Johnston. (*Electronic Tech.*, vol. 37, pp. 2–6; January, 1960.) A method is described for introducing the concepts of bearing and angle into fast Cartesian analog computations without the use of mechanical shafts and servomechanisms.

681.142:621.3.029.6 766

Microwave Computer Circuits—F. Leary. (*Electronics*, vol. 32, pp. 77–81; November 20, 1959.) Examples of the use of microwave components and techniques in the construction of simple high-speed computing elements are given. Main problems are the cost and complexity of the waveguide systems required.

681.142:621.376.22 767

Use of a Diode Ring as a Four-Quadrant Multiplier—R. H. Wilcox. *Rev. Sci. Instr.*, vol. 30, pp. 1009–1011; November, 1959.) The operation of a diode ring as a passive analog multiplier is analyzed. Tests show that an accuracy within 1 per cent is obtainable at input levels up to 150 mv.

681.142 768

Electronic Digital Computers [Book Review]—C. V. L. Smith. Publishers: McGraw-Hill, London, 443 pp. (*Electronic Tech.*, vol. 37, pp. 43–44; January, 1960.)

CIRCUITS AND CIRCUIT ELEMENTS

621.316.8:621.391.822 769

Noise of Resistors and Resistor Combinations without and with Load—K. Lunze. (*NachrTech.*, vol. 8, pp. 580–584; December, 1958.) Noise due to current flow in carbon-film-type resistors is particularly considered. The increase over thermal noise is controlled by a factor which depends on loading, film dimensions and the construction of the resistor; from this a formula is derived which contains a constant dependent on film material.

621.319.4 770

The Impedance of Non-quasistationary. Annular-Plate Capacitors—W. Buschbeck (*Telefunken Ztg.* vol. 32, pp. 23–28; March, 1959. English summary, p. 72.) The maximum permissible dimensions for the avoidance of self-resonance are calculated for high-frequency grid stopper and lead-through capacitors.

621.319.42.004.6 771

The Reliability and Life of Impregnated-Paper Capacitors—J. P. Pitts. (*Proc. IEE*, vol. 106, pp. 397–403; October, 1959. Discussion, pp. 403–408.) The construction of paper capacitors and the problems associated with failure in them are reviewed. Possible methods of prolonging life and reducing failures are discussed.

621.372.414 772

Coaxial Resonators with Helical Inner Conductor—W. W. Macalpine and R. O. Schildknecht. (Proc. IRE, vol. 47, pp. 2099–2105; December, 1959.) Resonators of small size can be designed for the VHF and HF ranges. Design formulas are simple, and have been confirmed by experiment.

621.372.44:621.372.6 773

General Energy Relations in Nonlinear Reactances—J. M. Manley and H. E. Rowe. (Proc. IRE, vol. 47, pp. 2115–2116; December, 1959.) An alternative derivation to that used earlier (2988 of 1956) is based on conservation of energy and the properties of the device.

621.372.44:621.372.6 774

A Simplified Derivation of the Manley and Rowe Power Relationships—J. E. Carroll. (*J. Electronics Control*, vol. 6, pp. 359–361; April, 1959.) *See* 773 above.

621.372.5 775

The Determination of Canonical Reactance Quadripoles with Prescribed Iterative Matrix—R. Unbehauen. (*Arch. elekt. Übertragung*, vol. 12, pp. 545–556; December, 1958.) The iterative matrix of any reactance quadripole is realized by means of canonical circuits (see, *e.g.*, 2354 of 1957). The method consists in developing a two-pole function into a continued fraction. This function represents the impedance of the two-pole network which results from terminating by unity resistance the output of a quadripole realizing the given matrix.

621.372.5 776

Applications of Wave Matrices for Calculations on Four-Terminal Networks with Transverse Symmetry—L. R. Yavich. (*Radiotekh. Elektron.*, vol. 4, pp. 341–344; February, 1959.) An extension of the method used in the classical theory of linear networks and based on bisecting the four-terminal network. See 2149 of 1959.

621.372.5:061.3 777

Modern Network Theory in Electrical Engineering—J. T. Allanson. (*Nature*, vol. 184, pp. 1691–1692; November 28, 1959.) Report of a conference held by the Department of Electrical Engineering of the University of Birmingham, September 22–24, 1959.

621.372.5:621.3.016.35 778

Some Considerations on the Stability of Electrical Circuits—I. Gumowski. (*Ann. Télécommun.*, vol. 13, pp. 121–124; May/June, 1958.) A definition of stability based on an integral equation is proposed. It is considered to be more general in applicability than the definitions of Bode and James and Weiss.

621.372.5:621.391.822:621.375.4 779

Contribution to the Theory of Noisy Quadripoles—R. Paul. (*NachrTech.*, vol. 8, pp. 548–568; December, 1958.) Detailed consideration of the parameters which determine the noise figure, particularly of transistors. The effect of circuit configuration on noise figure is discussed and typical circuit parameters for thermal-noise networks are tabulated. The noise characteristics of a single-stage transistor amplifier are investigated.

621.372.5.001.572 780

Transient Synthesizer—P. Eykhoff. (*Electronic Tech.*, vol. 37, pp. 31–36; January, 1960.) An instructional instrument is described which may be used to study the transient response of a quadripole of which the transfer function, in terms of poles and zeros, may be set immediately to the desired form.

621.372.51:621.375.42 781

Power Matching of Quadripoles with Complex Parameters—H. J. Butterweck. (*Arch. elekt. Übertragung*, vol. 12, pp. 540–544; December, 1958.) The passive matching impedances are derived which are required for maximum power amplification with quadripoles having complex parameters, such as transistors at high frequencies. A criterion is established for unconditional stability of a quadripole connected to passive impedances.

621.372.54 782

Monotonicity and Maximally Flat Rational Functions—T. R. O'Meara. (Proc. IRE, vol. 47, pp. 2116–2117; December, 1959.) It is shown that these functions describe the transmission properties for some common cases in loss-free filter design.

621.372.62 783

The Multipole Network with Symmetry of Terminal Number—W. Klein. (*Arch. elekt. Übertragung*, vol. 12, pp. 533–539; December, 1958.) Using matrix notation formulas are derived for crosstalk in multipole networks which have an equal number of input and output terminal pairs.

621.373:621.376.32 784

The Modulation of the Natural Frequency of a Loss-Free Oscillator Circuit—E. Kettel. (*Telefunken Ztg.*, vol. 31, pp. 254–261; December, 1958, and vol. 32, pp. 29–38; March, 1959. English summary.) The modulation can be represented by a Hill's equation. The properties of oscillator circuits with one or two controllable reactance elements are investigated, and equations of the ideal frequency modulator are derived.

621.373.4.029.65:376.23 785

Transistor Phase Detector for Phase-Lock Stabilization of a 30,000-Mc/s Klystron—R. W. Zimmerer. (*Rev. Sci. Instr.*, vol. 30, pp. 1052–1053; November, 1959.) A 15-mc reference signal is applied to the common emitters of two transistors with their bases driven in push-pull by the output of a 15-mc IF amplifier. A control signal is derived from the two collectors and is in series with the klystron repeller voltage supply. See 397 of 1958 (Thompson and Cateora).

621.373.42:621.316.729 786

Oscillator Synchronization at Combination Frequencies for the Purpose of Wide-Band Frequency Stabilization—G. M. Utkin. (*Radiotekh. Elektron.*, vol. 4, pp. 272–285; February, 1959.) Investigation of a system of three coupled oscillators, two of which are tuned to the natural frequency of the third oscillator.

621.373.42:621.316.729 787

Effect of an E.M.F. with Periodically Varying Parameters on an Oscillatory System——N. N. Lunacharskiĭ. (*Radiotekh. Elektron.*, vol. 4, pp. 286–294; February, 1959.) Mathematical analysis, based on the Ricatti equation with variable coefficients, to determine the phase variations in an oscillator with an applied EMF periodically varying in amplitude and frequency.

621.373.421.11 788

On the Possibility of Further Generalization in Quasilinear Theory of Single-Circuit LC Oscillators—P. G. Korolev. (*Radiotekh. Elektron.*, vol. 4, pp. 262–271; February, 1959.) A general expression is derived for the complex amplitude of the first harmonic of the oscillator anode current for a given tube characteristic and any arbitrary amplitude values of a synchronous or asynchronous EMF.

621.374.32:621.387.4 789

Millimicrosecond Discriminator—D. W. Swift and V. Perez-Mendez. (*Rev. Sci. Instr.*, vol. 30, pp. 1004–1006; November, 1959.) A discriminator circuit for use with counting equipment is described which has a good response to pulses as short as 3 mμsec.

621.374.34 790

10^{-9}-sec-Resolving-Time Coincidence Circuit-Limiting Effect in Electron Tubes—F. Lepri. (*Rev. Sci. Instr.*, vol. 30, pp. 1049–1050; November, 1959.) The operation of the circuit described is based on the formation of a virtual cathode between adjacent electrodes under positive grid conditions. Characteristic curves for a pentode Type E 180 F are shown. Tests performed on 50 tubes showed a spread of about 5 per cent in limited-current values.

621.374.4:621.372.44 791

Frequency Multiplication with Nonlinear Capacitors—a Circuit Analysis—D. B. Leeson and S. Weinreb. (Proc. IRE, vol. 47, pp. 2076–2084; December, 1959.) From the formulas given, it is possible to specify the optimum nonlinear characteristic for a given circuit and harmonic number, and to calculate the conditions for maximum efficiency. The procedure can be used for frequency division and for circuits with nonlinear inductors.

621.374.4:621.382.22 792

Two-Crystal Harmonic Generator—T. E. Hartman. (*Rev. Sci. Instr.*, vol. 30, pp. 1063–1064; November, 1959.) The Si crystals are small polished pieces of microwave-diode material with tungsten-wire cat whiskers. Input and output waveguides have their broad faces in contact. One whole crystal assembly is moved to tune the generator over the fundamental frequency range 22.8–24.3 kmc.

621.375.1.016.35 793

Multistage Amplifier Stability Design Criteria—L. G. Cripps. (*Electronic Radio Eng.*, vol. 36, pp. 454–458; December, 1959.) The stability of a cascade amplifier is considered for the two cases: where the stability factors of all the stages are equal a) before cascading, and b) after cascading. A short discussion of the results is given.

621.375.127 794

Push-Pull Amplifier Balance—(*Electronic Tech.*, vol. 37, pp. 41–43; January, 1960.) Negative voltage feedback may be applied independently to the two sides of a push-pull amplifier circuit by the insertion of an inductance and shunt resistance network in the lead to the primary center tap of the output transformer.

621.375.22:621.372.44 795

Reducing Amplifier Distortion—G. W. Holbrook. (*Electronic Tech.*, vol. 37, pp. 13–20; January, 1960.) A method is described for correcting the nonlinear distortion in tube amplifiers using metallic rectifiers as nonlinear resistances. Examples of corrected single-ended and push-pull amplifiers are given.

621.375.4 796

Some Design Considerations for High-Frequency Transistor Amplifiers—D. E. Thomas. (*Bell Syst. Tech. J.*, vol. 38, pp. 1551–1580; November, 1959.) The interaction between output and input due to internal feedback in the transistor is illustrated, and design data are developed for networks used to overcome this. Many practical amplifiers are simple and require a minimum of design effort.

621.375.9:538.569.4 797

Spin-Spin Energy Transfer and the Operation of Three-Level Masers—W. B. Mims and J. D. McGee. (Proc. IRE, vol. 47, p. 2120; December, 1959.)

621.375.9:538.569.4 798

Construction of a Strong-Field Maser-Type Type Self-Oscillator—C. Fric. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 80–82; July 6, 1959.) Proton spin resonance in a current of magnetically polarized water is applied in the design of a maser which operates in stable conditions without parasitic modulation. Its frequency is 29.66 mc corresponding to a field of 6980 gc. See also 2548 of 1959 (Benoit, *et al.*).

621.375.9:538.569.4 799

Operation of a Zero-Field X-Band Maser—J. E. King and R. W. Terhune. (*J. Appl. Phys.*, vol. 30, pp. 1844–1845; November, 1959.) Note on the operation of a 3-level maser amplifier at 12.3 kmc using iron-doped Al_2O_3 and only a small magnetic field for tuning.

621.375.9:538.569.4 800

Operating Characteristics of an Ammonia Beam Maser—F. S. Barnes. (Proc. IRE, vol. 47, pp. 2085–2098; December, 1959.) The simple theory is expanded to predict the angular distribution of the molecules leaving the collimator, and the effect of the focuser on the velocity distribution. Comparison with experimental data shows the importance of collisions and beam divergence. 51 references.

621.375.9:621.372.44 801

Parametric Amplification and Conversion in Propagating Circuits using Nonlinear Reactances—N. C. Chang. (Proc. IRE, vol. 47, p. 2117; December, 1959.) The case of a time-varying reactance coupling three propagating circuits is analyzed.

621.375.9:621.372.44 802

Noise Figure for a Travelling-Wave Parametric Amplifier of the Coupled-Mode Type—C. G. Shafer. (Proc. IRE, vol. 47, pp. 2117–2118; December, 1959.)

621.375.9:621.372.44:621.382.22 803

An Extremely Low-Noise 6-kmc/s Parametric Amplifier using Gallium Arsenide Point-Contact Diodes—M. Uenohara and W. M. Sharpless. (Proc. IRE, vol. 47, pp. 2114–2115; December, 1959.) Variation of excess noise temperature with diode temperature has been measured; a range of values comparable to that for a maser has been obtained. *See* also 805 below.

621.375.9:621.372.44:621.382.22 804

X-Band Parametric-Amplifier Noise Figures—B. C. De Loach and W. M. Sharpless. (Proc. IRE, vol. 47, p. 2115; December, 1959.) Two types of GaAs point-contact diode with improved gain-bandwidth properties have been examined. *See* also 803 above.

621.375.9:621.372.44:621.382.23 805

Low-Noise Parametric Amplifier using Germanium p-n Junction Diode at 6 kMc/s—M. Uenohara and A. E. Bakanowski. (Proc. IRE, vol. 47, pp. 2113–2114; December, 1959.) Experimental arrangements and results are given for noise-figure measurements at various bias voltages and temperatures.

GENERAL PHYSICS

535.62 806

Subjective Colour Tests—(*Wireless World*, vol. 66, pp. 33–34; January, 1960.) "Land colour" (3629 of 1959) is found to depend on subjective effects and picture composition to convey the color infomation to the mind of the observer. It does not, therefore, offer a practical system for color television.

537.227:539.2 807

Crystal Stability and the Theory of Ferroelectricity—W. Cochran. (*Phys. Rev. Lett.*, vol. 3, pp. 412–414; November 1, 1959.)

537.29:535.34 808

Influence of an Electric Field on an Optical Absorption Edge—W. Franz. (*Z. Naturforsch.*, vol. 13a, pp. 484–489; June, 1958.) The absorption edge displacement in a crystal with external field strength of the order of 10^5–10^6 volt/cm is interpreted.

537.311.3:536.2 809

Deviation from Matthiessen's Rule and Lattice Thermal Conductivity of Alloys—P. G. Klemens. (*Aust. J. Phys.*, vol. 12, pp. 199–202; June, 1959.) The difference in the ideal electronic thermal conductivity between an alloy and a pure metal can be estimated from the corresponding difference in the ideal electrical resistivity, using the Wiedemann-Franz law.

537.312.62 810

The Inverse Skin Effect—M. G. Haines. (*Proc. Phys. Soc.*, vol. 74, pp. 576–584; November 1, 1959.) The axial current density in an infinite cylindrical conductor is calculated as a function of radius and time. Rigid and radially expanding conductors are treated; current density distributions are obtained which sometimes have no resemblance to the normal skin effect.

537.32:536.7 811

Irreversible Thermodynamics and Kinetic Theory in the Derivation of Thermoelectric Relations—J. W. Leech. (*Canad. J. Phys.*, vol. 37, pp. 1044–1054; September, 1959.) Considerations of irreversible thermodynamics simplify the determination of thermoelectric coefficients using kinetic-theory arguments based on Boltzmann's equation. A new expression for Thomson's coefficient has been derived. Only simple models have been used but the theory is capable of extension to more complex ones.

537.56 812

The Structure of a Stream of Electrons and Ions Drifting and Diffusing in a Gas when Ionization by Collision and Molecular Attachment are Present—L. G. H. Huxley. (*Aust. J. Phys.*, vol. 12, pp. 171–183; June, 1959.)

537.56 813

Calculation of the Thermal Conductivity of an Ionic Current—H. Cabannes. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 47–49; July 6, 1959.) A thermal conductivity tensor for the ionic part of a plasma is derived from kinetic theory.

537.56 814

Electric Field Distributions in an Ionized Gas—M. Baranger and B. Mozer. (*Phys. Rev.*, vol. 115, pp. 521–525; August 1, 1959.) A method for improving systematically the Holtsmark distribution is described. It is then applied to the calculation of the distribution of the high-frequency component of the electric field in an ionized gas in thermal equilibrium.

537.56:538.56 815

Space-Charge Waves in Cylindrical Plasma Columns—A. W. Trivelpiece and R. W Gould. (*J. Appl. Phys.*, vol. 30, pp. 1784–1793; November, 1959.) The existence of space-charge waves in stationary plasmas of finite cross section has been demonstrated theoretically and experimentally. In addition to for ward waves, a plasma can support backward waves when there is a finite axial magnetic field. This makes possible the design of a backward-wave oscillator in which the plasma is the slow-wave circuit. Other possible applications are noted.

537.56:538.63 816

Electromotive Force in a Highly Ionized Plasma Moving Across a Magnetic Field—M. Sakantula, B. E. Clotfelter, W. B. Edwards, and R. G. Fowler. (*J. Appl. Phys.*, vol. 30, pp. 1669–1671; November, 1959.) The EMF is proportional to the flow speed. Oscillographic probe measurements of flow velocity and plasma resistance are described.

538.221 817

Statistical Mechanical Theory of a Random Ferromagnetic System—R. Brout. (*Phys. Rev.*, vol. 115, pp. 824–835; August 15, 1959.) Study of the behavior of solid solutions of paramagnetic impurities which are exchange-coupled in a nonmagnetic substrate yields a considerable amount of information about the nature of the exchange coupling and the temperature dependence of the spin system.

538.222:538.614 818

Study of the Paramagnetic Faraday Effect—J. Soutif-Guicherd. (*Ann. Télécommun.*, vol. 13, pp. 169–185 and 222–238; July/August and September/October, 1958.) From a study of propagation in a gyromagnetic medium the magnitude of the Faraday effect is determined as a function of the constant ξ of the medium. The theory is applied to rotation in paramagnetic salts, and curves are derived for the rotation angle s as a function of the applied field. A description is given of experimental apparatus, and results of measurements on Mn and Fe salts at wavelengths of 1 and 10 cm are compared with with theoretical calculations. 60 references. For an abbreviated report in English see *J. Appl. Phys.*, vol. 29, pp. 256–258; March, 1958.

538.3 819

Structure of the Electromagnetic Field—B. Bertotti. (*Phys. Rev.*, vol. 115, pp. 742–745; August 1, 1959.) A mathematical study of the structure of a curved space-time in which a source-free EM field is present.

538.3:517 820

Helical Fields—H. Poritsky.. (*J. Appl. Phys.*, vol. 30, pp. 1828–1837; November, 1959.) Simple analytic helically invariant solutions of the Laplace equation are given and combined to describe the electrostatic field of a charged helix, and the magnetic field of a helical electric current. Certain graphical flux plotting methods are outlined and illustrated, and network analogies are suggested for solving these fields.

538.3:530.145 821

Significance of Electromagnetic Potentials in the Quantum Theory—Y. Aharonov and D. Bohm. (*Phys. Rev.*, vol. 115, pp. 485–491; August 1, 1959.) Contrary to the conclusions of classical mechanics, there exist effects of potentials on charged particles, even in the region where all the fields vanish. The significance of this is discussed.

538.311 822

Microwave Magnetic Field near a Conducting Perturbation—D. S. Rodbell. (*J. Appl. Phys.*, vol. 30, pp. 1845–1846; November, 1959.) Experiments are described to show that locally intense microwave magnetic-field strengths can be obtained with low power levels by using a conductor to perturb the microwave electric field of a resonant cavity.

538.561:539.12 823

Radiation Produced by the Transit of Charged Particles near Ideally Conducting Bodies—Yu. N. Dnestrovskiĭ and D. P. Kostomarov. (*Radiotekh. Elektron.*, vol. 4, pp. 303–312; February, 1959.) Expressions are obtained for the energy and radiation spectrum. The excitation of oscillations by electrons entering a circular waveguide from an open half-space is discussed.

538.561:539.12:523.165 824

Radiation from Particles Exceeding the Velocity of Light, and Several Applications of it in Experimental Physics—P. A. Čerenkov. [*Science and Culture*, (Calcutta), vol. 25, pp. 281–286; November, 1959.] The history of the discovery and interpretation of Čerenkov radiation is outlined. The application of radiation measurements in the investigation of cosmic-ray showers is discussed.

538.566 825

Vertex-Excited Surface Waves on Both Faces of a Right-Angled Wedge—S. N. Karp and F. C. Karal, Jr. (*Commun. Pure Appl. Math.*, vol. 12, pp. 435–455; August, 1959.)

538.566:535.42]+534.26 826

Diffraction by an Infinite Slit—H. Levine. (*J. Appl. Phys.*, vol. 30, pp. 1673–1682; November, 1959.) A rigorous analysis of the problem for plane waves with special emphasis on short wavelengths and grazing incidence.

538.569.4:621.375.9 827

Construction of a Strong-Field Maser-Type Self-Oscillator—Fric. (*See* 798.)

538.691 828

On the Asymptotic Series Expansion of the Motion of a Charged Particle in Slowly Varying Fields—J. Berkowitz and C. S. Gardner. (*Commun. Pure Appl. Math.*, vol. 12, pp. 501–512; August, 1959.)

539.2:537.122 829

Self-Consistent Field Approach to the Many-Electron Problem—H. Ehrenreich and M. H. Cohen. (*Phys. Rev.*, vol. 115, pp. 786–790; August 15, 1959.) The self-consistent field method in which a many-electron system is described by a time-dependent interaction of a single electron with a self-consistent EM field is shown for many problems to be equivalent to the many-body treatment.

539.2:537.311.1 830

Electrodynamics of Charge Carriers of Negative Effective Mass in Crystals—S Rodriguez. (*Phys. Rev.*, vol. 115, pp. 821–823; August 15, 1959.) The transport properties of negative-effective-mass carriers in crystals are studied. The electrical conductivity of a sample in which the electron distribution function is weakly perturbed from its thermal equilibrium value is always positive, even in the presence of a magnetic field. Cyclotron resonance experiments in equilibrium should therefore display energy absorption.

539.2:538.569.4 831

Optical Pumping in Crystals—H. H. Theissing, P. J. Caplan, F. A. Dieter, and N. Rabbiner. (*Phys. Rev. Lett.*, vol. 3, pp. 460–462; November 15, 1959.) An estimate is made of the expected population change in the ground state of a crystal due to optical pumping.

539.2:538.569.4:621.372.413 832

The Coupling of a Spin System to a Cavity Mode—K. W. H. Stevens and B. Josephson, Jr. (*Proc. Phys. Soc.*, vol. 74, pp. 561–575; November 1, 1959.) A wave-mechanics treatment is given in which the expectation value of the z component of total spin angular momentum is determined. This problem has become important with recent developments in maser technology.

GEOPHYSICAL AND EXTRATERRESTRIAL PHENOMENA

523.152.3:621.396.96 833

The Determination of the Electron Density in Interplanetary Space—J. M. Kelso. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 357–359; November, 1959.) The average electron density and the arc length of the ray path from a space vehicle to the ground can be measured by transmitting a pulse to the vehicle on one VHF frequency and receiving pulses emitted from a transponder in the vehicle on this and on a different frequency. In this way, electron densities of the order of 100 electrons/cm^3 can be estimated.

523.16 834

The Temperature required for Nuclear Reactions in Cosmical Electrical Discharges—C. E. R. Bruce. (*Nature*, vol. 184, suppl. no. 26, pp. 2004–2005 December 26, 1959.) It is probable that at a temperature of about 4×10^{80}K nuclear reactions occur freely.

523.164 835

Technical and Astronomical Measurements with the Bonn 25-m Radio Telescope—P. G. Mezger. (*Telefunken Ztg.*, vol. 31, pp. 213–225; December, 1958, and vol. 32, pp. 38–46; March, 1959. English summary.) Details are given of operational tests on the receiving installation of the Bonn University radio telescope on the Stockert [see 3845 of 1957 (Pederzani)]. Additions to the receiving equipment, and the calibration of the antenna by series of astronomical measurements and comparisons with results from other radio telescopes are also described.

523.164 836

The Positional Accuracy of the 25-m Radio Telescope of the Bonn Observatory—B. H. Grahl. (*Telefunken Ztg.*, vol. 31, pp. 226–232; December, 1958. English summary, pp. 272–273.) The tracking system and its adjustment and control are described. Details are also given of the alignment of the telescope axes and the correction of mechanical inaccuracies of the reflector structure.

523.164:551.510.535 837

Radio-Star Scintillations and Ionospheric Disturbances—T. R. Hartz. (*Canad. J. Phys.*, vol. 37. pp. 1137–1152; October, 1959.) Spread-*F* phenomena are not adequate to explain scintillations at 53 mc at Ottawa and precipitation of solar particles seems to be involved at high latitudes.

523.164:551.510.535 838

Cosmic Radio Noise Absorption on 25 Mc/s and F. Scatter—K. R. Ramanathan and R. V. Bhonsle. (*J. Geophys. Res.*, vol. 64, pp. 1635-1637; October, 1959.) A close connection is suggested between the observed anomalous enhancement of scattered VHF signals and the post-sunset increase in the attenuation of cosmic noise.

523.164.3 839

Observation of the Central Region of the Galaxy at 33.3 cm λ with the Large Radio Telescope of the G.A.O. [Principal Astronomical Observatory]—V. G. Malumyan. (*Dokl. Akad. Nauk SSSR*, vol. 129, pp. 1003–1004; December 11, 1959.) A note on radio-telescope observations of Sagittarius made in June, 1959, with a receiver of 60-mc bandwidth and antenna temperature sensitivity <1°K with a 5-second time-constant. Recordings show two brightness components with half-widths respectively 5' and 1.25°. Observations were also made at 3.2 and 9.4 cm λ.

523.164.3 840

Observation of the Sagittarius-A Radio Source at High Resoultion—Yu. N. Parilskiĭ.

Dokl. Akad. Nauk SSSR, vol. 129, pp. 1261–1263; December 21, 1959.) Description of observations carried out in April, 1959, by the Pulkovo radio telescope. Graphs show the complex structure of the source. *See* 839 above.

523.164.3 841

Neutral Hydrogen Gas in the Taurus-Orion Region observed with a Multichannel 21-cm Line Receiver—R. X. McGee and J. D. Murray. (*Aust. J. Phys.*, vol. 12, pp. 127–133; June, 1959.)

523.164.32:523.165 842

Solar Radio Bursts and Low-Energy Cosmic Rays—A. R. Thompson and A. Maxwell. (*Nature*, vol. 185, pp. 89–90; January 9, 1960.) Events following a solar flare are elucidated from a study of the relation between continuum radiation [1126 *1* of 1958 (Maxwell, *et al.*)] and the occurrence of enhanced proton flux at the earth.

523.164.32:523.755 843

On the Correlation of Solar Noise Fluctuations in Harmonically Related Bands—L. R. O. Storey. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 293–296; November/December, 1959.) A method is proposed for the study of the solar corona; a delayed correlation between rapid fluctuations of enhanced solar radio emission (Type II) in harmonically related frequency bands would be observed.

523.164.4 844

Occultations of the Crab Nebula by the Solar Corona in June 1957 and 1958—O. B. Slee, (*Aust. J. Phys.*, vol. 12, pp. 134–156; June, 1959.) The distribution of 85.5-mc radiation on days when the angular separation is less than 10 solar radii is not consistent with a symmetrical scattering process; better agreement is obtained by postulating the existence of scattering and regular refraction of comparable magnitude.

523.165 845

Energy Spectrum of the Heavy Nuclei in the Cosmic Radiation between 7- and 100-BeV/Nucleon—P. L. Jain, E. Lohrmann, and M. W. Teucher. (*Phys. Rev.*, vol. 115, pp. 654–659; August 1, 1959.) From observations it is concluded that a power spectrum of the form $E^{1.6}$ (where E=energy/nucleon) holds for heavy nuclei energies up to 100 bev/nucleon and for α particles up to 7 bev. With certain assumptions, the same exponent is a satisfactory value for the spectrum of α particles for energies up to 1500 bev.

523.165 846

The Onset Times of Forbush-Type Cosmic-Ray Intensity Decreases—A. G. Fenton, K. G. McCracken, D. C. Rose, and B. G. Wilson. (*Canad. J. Phys.*, vol. 37, pp. 970–982; September, 1959.)

523.165 847

A Comparison of the Cosmic-Ray Intensity at High Altitudes with the Nucleonic Component at Ground Elevation—J. E. Henkel, J. A. Lockwood, and J. H. Trainor. (*J. Geophys. Res.*, vol. 64, pp. 1427–1438; October, 1959.) Results of balloon-borne soundings with single Geiger tubes are compared with those made by a nucleonic detector on Mount Washington at 1909-meter height.

523.165 848

On the Structure of Extensive Cosmic-Ray Air Showers: the Penetrating Component—E. W. Kellermann and N. Dickinson. (*Proc. Phys. Soc.*, vol. 74, pp. 554–560; November 1, 1959.)

523.165 849

Momentum Spectrum of the Van Allen Radiation—H. Alfvén. (*Phys. Rev. Lett.*, vol. 3, pp. 459–460; November 15, 1959.) The spectrum appears to obey the same power law as cosmic radiation indicating that the Van Allen radiation may be explained by the mechanism responsible for the acceleration of cosmic radiation.

523.3 850

Absence of Craters on the Far Side of the Moon—D. B. Beard. (*Nature*, vol. 184, suppl. no. 21, p. 1631; November 21, 1959.) The reported lower incidence of craters on the far side of the moon may be explained by the effect of the earth's gravitational field on meteoric material in orbit about the sun.

523.3:551.507.362.1 851

Observations related to the Impact of Lunik II—G. Fielder. (*Nature*, vol. 185, p. 11; January 2, 1960.) A table is given of the results of a number of independent observations of the impact of Lunik II with the moon. See also 4051 of 1959 (Davies and Lovell).

523.:551.507.362.2 852

First Results Derived from the Photographs of the Moon's Far Side—N. P. Barabashov and Yu. N. Lipskiĭ. (*Dokl. Akad. Nauk SSSR*, vol. 129, pp. 1000–1002; December 11, 1959.) Photographs taken by the third soviet cosmic rocket launched October 4, 1959, are shown. During 40 minutes of camera operation, numerous photographs were taken of the moon's far side at distances 65,200 to 68,400 km from its surface.

523.5:621.396.9 853

The Temporal Variation of the Heights of Reflection Points of Meteor Trails—A. A. Weiss. (*Aust. J. Phys.*, vol. 12, pp. 116–126; June, 1959.) There is no significant seasonal variation in either the mean height or the width of the height distribution. The mean height alone shows a diurnal variation with maximum height near midnight. Both height parameters depend on the zenith angle of the apex of the earth's way.

523.5:621.396.9 854

Air Motions and the Fading, Diversity, and Aspect Sensitivity of Meteoric Echoes—L. A. Manning. (*J. Geophys. Res.*, vol. 64, pp. 1415–1425; October, 1959.) A theory is given of meteoric reflection from distorted trails. Experimental results confirm the predictions and facilitate a determination of the principal properties of the wind profile.

523.5:621.396.9 855

Meteor Radiation Distributions and the Radio-Echo Rates Observed by Forward Scatter—M. L. Meeks and J. C. James. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 228–235; November, 1959.) The diurnal variations observed by forward scatter over three different paths are found to be in reasonable agreement with predictions made using a simplified model distribution based on the radar data of Hawkins (*Astrophys. J.*, vol. 61, p. 386; 1956.

523.5:621.396.9 856

Turbulence at Altitudes of 80–100 km and its Effects on Long-Duration Meteor Echoes—J. S. Greenhow and E. L. Neufeld. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 384–392; November, 1959.) The characteristics of the echoes can be readily explained in terms of multiple reflections from overdense columns of ionization and are not consistent with the theory of incoherent scattering from underdense columns.

523.746.5 857

Prediction of Sunspot Numbers for Cycle 20—W. B. Chadwick. (*Nature*, vol. 184, suppl. no. 23, p. 1787; December 5, 1959.) Comment on 3282 of 1959 (Herrinck).

550.38 858

Note on Conjugate Points of Geomagnetic Field Lines for some Selected Auroral and Whistler Stations of the I. G. Y.—E. H. Vestine. (*J. Geophys. Res.*, vol. 64, pp. 1411–1414; October, 1959.) A method of deriving conjugate points of some auroral and magnetic stations of the I. G. Y.

550.385 859

Geomagnetic Oscillations at Middle Latitudes: Parts 1 and 2—E. Maple (*J. Geophys. Res.*, vol. 64, pp. 1395–1409; October, 1959.) Observations of geomagnetic fluctuations in the frequency range 1–0.005 cps, are discussed, based on measurements at Tucson, Ariz. The results favor the hypothesis of intralayer hydromagnetic resonance in the ionosphere as the source mechanism.

550.385 860

Geomagnetic Activity at Halley Bay on Disturbed Days—J. MacDowall. (*Nature*, vol. 184, pp. 1543–1545; November 14, 1959.) Diurnal variations of geomagnetic activity on disturbed days are related to auroral and ionospheric effects. An analysis of five worldwide sudden storm commencements (SSC) shows positive departures of the horizontal field before midnight and negative departures after midnight.

550.385:550.37 861

The Relation between H- and Z-Variations near the Equatorial Electrojet—C. A. Onwumechilli. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 274–282; November, 1959.) Small fluctuations in H and Z are strongly correlated particularly during daylight hours. The ratio of the amplitudes of the components during these fluctuations shows a marked dirunal variation but is almost constant during the day.

550.385.26 862

Note on the Tidal Theory of the S_q Magnetic Field—R. L. Ingraham. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 263–273; November, 1959.) The solar quiet day magnetic field has a diurnal component which is roughly a thousand times greater than expected on tidal theory. Possible explanations are given.

550.385.4 863

Hydromagnetic Propagation of Sudden Commencements of Magnetic Storms—W. E. Francis, M. I. Green, and A. J. Dessler. (*J. Geophys. Res.*, vol. 64, pp. 1643–1645; October, 1959.) A brief analysis of hydromagnetic propagation, which gives an expression for the transit time of waves traveling in the earth's equatorial plane.

550.389.2 864

The International Geophysical Year 1957–58—D. Brunt. (*Proc. IEE*, pt. B, vol. 106, pp. 437–443; September, 1959.) Research carried out during the I.G.Y. in different branches of geophysics is reviewed. Attention is drawn to new concepts already established and to those probably true.

551.507.362.2+629.19 865

Space Probes and Satellites—[*Engineering*, (*London*), vol. 187, pp. 615–616; May 8, 1959.] A summary of the main details of all satellite and space-vehicle launchings up to April 13, 1959.

551.507.362.2 866

Temperature Stabilization of Highly Reflecting Spherical Satellites—G. Hass, L. F. Drummeter, Jr., and M. Schach. (*J. Opt. Soc. Amer.*, vol. 49, pp. 918–924; September, 1959.)

551.507.362.2 867

A Correction Necessary for the Application of the Doppler Effect to the Measurements of

Distances to Satellites—J. M. Brito, Jr. (PROC. IRE, vol. 47, p. 2023; November, 1959.) The use of spherical-earth geometry gives a value for minimum passing range considerably lower than that obtained from plane-earth geometry.

551.507.362.2 868

The Fluctuations of the Acceleration of Satellites—H. K. Paetzold. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 259–262; November, 1959.) The fluctuations are associated with changes in air density at perigee height. These density variations may be associated with changes in sunspot activity; they are, in any case, certainly due to variable heating at the perigee height.

551.507.362.2 869

A Method for Measuring Local Electron Density from an Artificial Satellite —L. R. O. Storey. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 325–340; November /December, 1959.) A proposal for a satellite equipped to measure the electric and magnetic fields in the radio wave set up in the neighborhood of the satellite by "whistler"-mode transmission from a ground-based VLF transmitter. From the wave impedance given by the ratio of the fields the local electron density could be deduced.

551.510.52 870

Applications of the Molecular Refractivity in Radio Meteorology —B. R. Bean and R. M. Gallet. (*J. Geophys. Res.*, vol. 64, pp. 1439–1444; October, 1959.) A discussion of the advantages of molecular refractivity as a significant parameter in studies of climatic differences and air mass characteristics.

551.510.52:621.391.812.621.1 871

Radio-Refractive-Index Climate Near the Ground—B. R. Bean and J. D. Horn. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 259–271; November/December, 1959.) World-wide maps of refractive index contours are given. The index varies systematically with climate, and is most accurately deduced from charts of the reduced-to-sea-level index.

551.510.52:621.391.812.621.1 872

Central Radio Propagation Laboratory Exponential Reference Atmosphere—B. R. Bean and G. D. Thayer. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 315–317; November/December, 1959.) A model for the variation of atmospheric refractive index with height is proposed which gives more accurate radio-ray profiles than the 4/3 earth radius treatment. A sample table of ray profiles is given.

551.510.53 873

Analytic and Experimental Electrical Conductivity between the Stratosphere and the Ionosphere—R. E. Bourdeau, E. C. Whipple, Jr, and J. F. Clark. (*J. Geophys. Res.*, vol. 64, pp. 1363–1370; October, 1959.) Results for the height range 35–80 km obtained from rocket soundings are compared with predicted values based on ion equilibrium and ionization by cosmic rays only.

551.510.535 874

Detection of an Electrical Current in the Ionosphere above Greenland—L. J. Cahill, Jr. (*J. Geophys. Res.*, vol. 64, pp. 1377–1380; October, 1959.) A description of measurements made on August 6, 1957, using a rocket-borne magnetometer. The average current density of the layer detected was about 11A/km^2.

551.510.535 875

Langmuir Probe Measurements in the Ionosphere—R. L. Boggess, L. H. Brace, and N. W. Spencer. (*J. Geophys. Res.*, vol. 64, pp. 1627–1630; October, 1959.) Measurements are described of electron temperature and positive-ion number density of the *E* layer above Fort Churchill, Manitoba, Canada, on November 30, 1958.

551.510.535 876

Note on Quiet-Day Vertical Cross-Sections of the Ionosphere along 75°W Geographic Meridian—J. W. Wright. (*J. Geophys. Res.*, vol. 64, pp. 1631–1634; October, 1959.) A discussion of results now being obtained from stations on the 75th meridian.

551.510.535 877

Gyro-Frequency in the Ionospheric Regions —S. Datta and R. N. Datta. (*Indian J. Phys.*, vol. 33, pp. 316–324; July, 1959.) Experimental results show that the magnetic fields calculated from gyro frequencies in the *E*, *F*, and F_2 regions are higher than expected. The *E*-region gyrofrequency has a marked semidiurnal variation with a minimum at midday.

551.510.535 878

An Investigation of the Ionospheric D Region—J. A. Fejer and R. W. Vice. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 291–306; November, 1959.) A model of the lower ionosphere between 68 km and 85 km is obtained from the observation of weak echoes from the D region and the measurement of ionospheric wave interaction.

551.510.535 879

Some Measurements of Collision Frequency in the E Region of the Ionosphere—D. M. Schlapp. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 340–343; November, 1959.) Measurements are made by observing how the deviative absorption of a radio echo varies with changes in its group path as a critical frequency is approached. Collision frequency at a fixed height seems to increase with solar activity.

551.510.535 880

E-Region Winds—W. H. Ward. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 394–395; November 1959.) The suggestion that heating of the E, region by the sun is responsible for E-region winds is supported by some experimental results. See also 3259 of 1955 (Greenhow and Neufeld).

551.510.535 881

A Relation between Giant Travelling Disturbances and Sporadic-E Ionization—L. H. Heisler. (*Nature*, vol. 184, suppl. no. 23, pp. 1788–1789; December 5, 1959.) Ionosonde records for the period July 10–28, 1955, show a relation between E_s anomalies and traveling disturbances. Sequential E_s [1899 of 1951 (McNicol and Gipps)] and F_2 cusp-type anomalies [1434 of 1957 (Munro and Heisler)] are also discussed in relation to these disturbances.

551.510.535 882

Two Anomalies in the Behaviour of the F_2 Layer of the Ionosphere—S. Croom, A. Robbins, and J. O. Thomas. (*Nature*, vol. 184, suppl. no. 26, pp. 2003–2004; December 26, 1959.) Report of a study of electron-density data at a number of widely distributed observatories during equinox in a year of high sunspot activity. Results show that the "geomagnetic anomaly" described by Appleton (1337 of 1955) extends much farther from the magnetic equator as lower heights are investigated. A diurnal asymmetry also exists, with forenoon electron densities greater than corresponding afternoon ones.

551.510.535 883

Some Remarks on Motion of Ionospheric Irregularity—N. Matuura. (*Rept. Ionosphere Space Research Japan*, vol. 13, pp. 4–20; March, 1959. Discussion.) The relative motion between irregularities in electron density and their surroundings is discussed. Two treatments of the problem are considered: the surrounding ionization being assumed to be a) a hydromagnetic fluid, and b) a fully ionized gas.

551.510.535 884

The Motion of Irregularities in the Ionosphere—T. Tsuda. (*Rept. Ionosphere Space Research Japan*, vol. 13, pp. 56–61; March, 1959. Discussion.) The mean velocity of irregularities in electron density is determined using simple turbulence theory. The irregularities move with the same velocity as the winds in the E region but there is a marked difference from wind velocity in the F region.

551.510.535 885

World-Wide Measurements of Horizontal Ionospheric Drifts—T. Shimazaki. (*Rept. Ionosphere Space Research Japan*, vol. 13, pp. 21–47; March, 1959. Discussion.) A critical survey is made of radio techniques for measuring horizontal drifts. A comparison is then made of results obtained during the I.G.Y. using the closely-spaced-receiver method which discloses seasonal and latitudinal differences in the diurnal variation of drifts. Tentative explanations of these results are given.

551.510.535 886

Ionospheric Drifts at Yamagawa in Japan—K. Tsukamoto and Y. Ogata. (*Rept. Ionosphere Space Research Japan*, vol. 13, pp. 48–55; March, 1959. Discussion.) Drift speeds, diurnal variations of the drift vector, and the relation between speed and geomagnetic activity are discussed using results obtained during about one year from August, 1957.

551.510.535 887

Ionized Irregularities and Wind Motion in the Ionosphere—S. Kato. (*Rept. Ionosphere Space Research Japan*, vol. 13, pp. 62–78; March, 1959. Discussion.) The motion of irregularities in electron density are studied on the basis of a three-dimensional model. Electrodynamic effects are slight in the E region under magnetically quiet conditions but are appreciable in the F region and even in the E region for disturbed conditions at high latitudes. A general discussion on the stability and lifetime of regions of irregular electron density is given.

551.510.535 888

Horizontal Winds and Ionization Drifts in the Ionosphere—H. Maeda. (*Rept. Ionosphere Space Research Japan*, vol. 13, pp. 79–90; March, 1959. Discussion.) From a study of geomagnetic observations during the International Polar Year, 1932–1933, it is concluded that ionization drifts in the F region are due to an applied electric field and not to air movement, while in the E region the ionization drift is almost the same as the air movement.

551.510.535 889

Horizontal Drifts in the E Region at Waltair—R. R. Rao and B. R. Rao. (*Nature*, vol. 185, pp. 27–28; January 2, 1960.) Results of an analysis of data obtained over a two-year period. A 24-hourly east-west component predominates.

551.510.535 890

Study of "Winds" in the F Region of the Ionosphere during the Unusual Days in the I.G.Y. Calendar—R. N. Singh and S. R. Khastgir. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 376–383; November, 1959.) Fading records were taken at 3.8–4.2 mc on three spaced receivers at Banaras. The experimental results are described and the fading records discussed with reference to the random and steady movement of irregularities.

551.510.535:523.5:621.396.96 891

A Theory for determining Upper-Atmos-

phere Winds from Radio Observations on Meteor Trails—G. V. Groves. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 344–356; November, 1959.)

551.510.535:523.78 892

The Effects of a Solar Eclipse on a Stratified Ionosphere—J. A. Gledhill. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 360–366; November, 1959.) The form of the isoelectronic surfaces in a three-layer ionosphere during an eclipse have been calculated. Tilts in these surfaces may lead to difficulties in the interpretation of ionograms.

551.510.535:523.78 893

The Behaviour of the Ionosphere over Cape Town and Johannesburg during the Annular Solar Eclipse of 25 December 1954—J. A. Gledhill. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 367–375; November, 1959.) It was not possible to explain the ionospheric changes at Cape Town, Johannesburg and Grahamstown in terms of a single solar brightness model. Oblique reflections may have affected the ionograms. There is some evidence that $\alpha'E = 4 \times 10^{-8} cm^3 second^{-1}$.

551.510.535:621.391.812.63 894

The Frequency Dependence of Ionospheric Absorption—K. Bibl, A. Paul, and K. Rawer. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 324–339; November, 1959. In German.) The total absorption was formerly expressed as a function of nondeviative D-layer plus deviative E-layer absorption [985 of 1952 (Bibl and Rawer)]. The expression has been modified to include the effect of a thin E_s layer. Experimental data are discussed in the light of the new theory.

551.510.535:621.391.812.63 895

The Absorption of Short Radio Waves in the D, E and F Regions of the Ionosphere—J. D. Whitehead. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 283–290; November, 1959.) Values of noon absorption at Slough from 1947 to 1953 have been analyzed. The electron collision frequencies for the E and F regions have been calculated and the variations of D-region absorption with sunspot number examined. The significance of the results is discussed.

551.510.535:621.391.812.63 896

The Use of Full-Wave Solutions in the Interpretation of Ionospheric Absorption Measurements—J. A. Fejer and R. W. Vice. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 307–317; November, 1959.) A full-wave correction is given which can be made to the usual Appleton-Hartree absorption calculation. Examples show that for a frequency of 2 mc this correction cannot be neglected.

551.510.535:621.396.96:523.3 897

Measurements of Ionospheric Electron Content by the Lunar Radio Technique—S. J. Bauer and F. B. Daniels. (*J. Geophys. Res.*, vol. 64, pp. 1371–1376; October, 1959.) Measurements of the Faraday rotation of lunar radio echoes at 151 mc are used to determine the time variation in the total ionospheric electron content. Absolute values of electron content are derived from data on the electron content below the F_2 peak computed from vertical-incidence experiments.

551.593 898

Excitation Mechanisms of the Oxygen 5577 Emission in the Upper Atmosphere—E. Tandberg-Hanssen and F. E. Roach. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 319–324; November/December, 1959.) Photochemical reactions affected by mass motions, and direct excitation due to mass motions are examined.

551.594.5+551.593 899

Auroral and Nightglow Observations at Ås, Norway—G. Kvifte. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 252–258; November, 1959.) More precise wavelength measurements are given for bands of the Meinel OH system in the nightglow.

551.594.5 900

Photometric Observations of Subvisual Red Auroral Arcs at Middle Latitudes—R. A. Duncan. (*Aust. J. Phys.*, vol. 12, pp. 197–198; June, 1959.) The arcs have been observed on the night following a bright visual aurora at a time when the magnetic disturbance index had fallen to five or less.

551.594.5 901

The Southern Auroral Zone in Geomagnetic Longitude Sector 20°E—S. Evans and G. M. Thomas. (*J. Geophys. Res.*, vol. 64, pp. 1381–1388; October, 1959.) Visual auroral observations at Antartic bases are tabulated to show the variation of the frequency of aurora occurrences with geomagnetic latitude between 63° and 79°.

551.594.5 902

Antartic Auroral Observations, Ellsworth Station, 1957—J. M. Malville. (*J. Geophys. Res.*, vol. 64, pp. 1389–1393; October, 1959.) A summary of auroral observations made during the antarctic winter of 1957. Evidence is obtained of a spiraling zone of maximum auroral activity.

551.594.5 903

Spectroscopic Observations of the Great Aurora of 10 February 1958: Parts 1 and 2—K. C. Clark and A. E. Belon. (*J. Atmos. Terr. Phys.*, vol. 16, pp. 205–227; November, 1959.) Spectrograms show an enhancement of vibrational excitation in the $B(F^2\Sigma_u{}^+)$ state of $N_2{}^+$ which can be attributed to a charge exchange process in a strong proton shower. These spectrograms also show a large number of atomic lines seldom seen, most of which are due to *OI* and N *II* transitions.

551.594.5 904

A Monochromatic Low-Latitude Aurora—F. E. Roach and E. Marovich. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 297–301; November/December, 1959.) A particular monochromatic auroral arc (6300Å) which occurred over Colorado, September 29–30, 1957, is described. It seems to have been a continuation of a similar one observed in France.

551.594.6 905

Telluric Origin of the Whistler Medium—F. S. Johnson. (*Nature*, vol. 184, suppl. no. 23, pp. 1787–1788; December 5, 1959.) Arguments are presented to show that the medium cannot be of solar or interplanetary origin and a mechanism is suggested for a telluric origin.

551.594.6 906

Effect of Latitude on the Diurnal Maximum of "Dawn Chorus"—J. H. Pope. (*Nature*, vol. 185, pp. 87–88; January 9, 1960.) Observations of the local time of diurnal maximum have been made at 16 stations. Analysis based on an eccentric dipole field is useful when considering "dawn chorus" theories.

521.030:537.5 907

Cosmic Electrodynamics. (Book Review)—J. W. Dungey, Publishers: University Press, Cambridge, 183 pp.; 1958. (*Nature*, vol. 184, pp. 1672–1673; November 28, 1959.) This book, bearing a similar title to that by Alfvén (see 2777 of 1950), indicates the progress and consolidation achieved in the field during the intervening decade.

LOCATION AND AIDS TO NAVIGATION

621.396.96 908

Optical Simulation of Radar Resolution—R. D. Rawcliffe, W. W. Lichtenberger, and H. V. Krone. (*J. Opt. Soc. Amer.*, vol. 49, pp. 887–890; September, 1959.) An optical simulator has been constructed in which the high resolution of an aerial photograph is degraded by known amounts in order to determine the radar resolution required to achieve a given target detectability.

621.396.96:621.396.934 909

Low-Cost Active Radar for Miss-Distance Data—W. H. Doty. (*Electronics*, vol. 32, pp. 91–93; November 20, 1959.) Frequency-sweep radar located within the target gives a direct indication of the miss distance.

621.396.965.4:534.88 910

Underwater Echo-Ranging with Electronic Sector Scanning: Sea Trials on *R.R.S. Discovery II*—Tucker, Welsby, Kay, Tucker, Stubbs, and Henderson. (*See* 745.)

621.396.967 911

The Line Elements between Transmitter and Aerial of a Radar Installation and their their Influence on Transmitter Frequency Stability—H. Schwindling. (*Telefunken Ztg*, vol. 31, pp. 242–253; December, 1958. English summary, pp. 273–274.) An airport surveillance radar installation is examined with regard to stability conditions governed by the "long-line" effect (3653 of 1958). The maintenance of stability by means of phase shifters can only be carried out by referring to the frequency spectrum of the transmitted pulses.

MATERIALS AND SUBSIDIARY TECHNIQUES

535.215 912

The Theory of Glow Curves—K. W. Böer, S. Oberländer, and J. Voight. (*Z. Naturforsch.*, vol. 13a, pp. 544–547; July, 1958.) The analysis of trapping-center distribution on the basis of glow curves and allowing for retrapping is considered. See also 3321 of 1959.

535.215 913

Gain-Bandwidth Product of Photoconductors—R. W. Redington. (*Phys. Rev.*, vol. 115, pp. 894–896; August 15, 1959.) Extension of earlier treatment (1914 of 1958) to include an arbitrary distribution of impurity levels. Results show the reciprocal of the relaxation time to be an upper limit for the gain-bandwidth product of a photoconductor with space-charge-limited dark current.

535.215:546.48'221 914

Dislocations in CdS Crystals and their Significance in Photoconductivity—E. Votava. (*Z. Naturforsch.*, vol. 13a, pp. 542–544; July, 1958. plate.) Methods of growing crystals with pronounced dislocations and of making these visible are discussed. Experiments seem to confirm that dislocations may reduce the electron lifetime.

535.215:546.48'221 915

The Electrical Behaviour of CdS Single Crystals with Voltage Pulses in the Breakdown Region—K. W. Böer, J. Dziesiaty, and U. Kümmel. (*Z. Naturforsch.*, vol. 13a, pp. 560–562; July, 1958.) Crystal current is plotted as a function of pulse width, amplitude and repetition frequency and comparisons are made with dc measurements at breakdown field strength. [see also 2749 of 1958 (Böer and Kümmel)].

535.215:546.863'221 916

Cathodoconductivity of Antimony Sulphide—Ya. A. Oksman and G. P. Tikhomirov (*Radiotekh. Elektron.*, vol. 4, pp. 344–346 February, 1959.) Investigation of the possibility of increasing the conductivity of thin dielectric and semiconductor films by electron bombardment for the purpose of amplifying the photoelectron emission current. The limiting values of the gains which can be obtained using these films at room temperature are determined. See 2458 of 1957 (Oksman).

535.37:546.47’221 917

Optical Properties of Activated and Unactivated Hexagonal ZnS Single Crystals—S. P. Keller and G. D. Pettit. (*Phys. Rev.*, vol. 115, pp. 526–536; August 1, 1959.) Further measurements on the polarization effects in the transmission spectrum of unactivated ZnS show that theoretical prediction holds except in the region 290–325 mμλ. The wavelength dependence and the polarization of the excitation and fluorescence spectra of the activated and unactivated crystals were measured at room temperature and at 77°K.

535.376 918

Energy Limit for Electroenhancement and Electroextinction Effects—G. Destriau. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 245–247; July 15, 1959.) The sensitivity of luminescent compounds of the CdZnS-Mn, *X* type under electron bombardment is enhanced by X-ray and reduced by ultraviolet-ray excitation. Extrapolation of experimental curves indicates that with an activation energy below 5000 ev no electroenhancement occurs.

535.376 919

New Effect of Sensitization to the Action of X Rays, by means of Infrared, in Luminescent Products of the Type CdZnS-Mn, *X*—F. Pingault. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 248–250; July 15, 1959.) Infrared radiation produces an enhancement effect similar to that described by Destriau (*see, e.g.* 918 above). The analogy between the action of an applied electric field and infrared irradiation is stressed.

535.376:546.48’221 920

Some Effects of Low Fields on Luminescence of CdS—C. E. Bleil and D. D. Snyder. (*J. Appl. Phys.*, vol. 30, pp. 1699–1702; November, 1959.) Experimental results are given for the shift of cathodoluminescence peaks with applied field and for the dependence of conductivity on voltage and irradiation. An explanation is suggested.

537.227 921

Asymmetric Hysteresis Loops and the Pyroelectric Effect in Triglycine Sulphate—A. Savage and R. C. Miller. (*J. Appl. Phys.*, vol. 30, pp. 1646–1648; November, 1959.) The apparent asymmetry, as disclosed by pyroelectric measurements, is shown to be due to electrode edge effects.

537.227 922

Domain Processes in Lead Titanate Zirconate and Barium Titanate Ceramics—D. Berlincourt and H. H. A. Krueger. (*J. Appl. Phys.*, vol. 30, pp. 1804–1810; November, 1959.) An experimental investigation of domain reorientation during poling, and domain switching processes under high mechanical or electric stress.

537.227:546.431’824–31 923

On the Dependence of the Switching Time of Barium Titanate Crystals on their Thickness—M. E. Drougard and R. Landauer. (*J. Appl. Phys.*, vol. 30, pp. 1663–1668; November, 1959.) Analysis of domain motion and field calculations show that the dependence of switching rate on thickness is explained by a monomolecular surface layer having an irreversible polarization and a low dielectric constant. Implications of this in explaining the switching mechanism are discussed.

537.311.31:538.63 924

Magnetoresistance of Copper—J. de Launay, R. L. Dolecek, and R. T. Webber. (*J. Phys. Chem. Solids*, vol. 11, pp. 37–42; September, 1959.) Report and discussion of measurements at 297°, 78° and 4.2°K in transverse and in longitudinal fields up to 100 kg.

537.311.33 925

Electric Conduction in Semiconductors—H. Fröhlich and G. L. Sewell. (*Proc. Phys. Soc.*, vol. 74, pp. 643–647; November 1, 1959.) In semiconductors with low mobility the usual theory of conduction is invalid. An expression for mobility is derived which should apply in such cases under certain conditions.

537.311.33 926

Volume and Surface Recombination of Injected Carriers in Cylindrical Semiconductor Ingots—J. P. McKelvey. (IRE Trans. on Electron Devices, vol. ED-5, pp. 260–264; October, 1958. Abstract, Proc. IRE, vol. 47, p. 495; March, 1959.)

537.311.33 927

Metal-to-Semiconductor Contacts: Injection or Extraction for Either Direction of Current Flow—N. J. Harrick. (*Phys. Rev.*, vol. 115, pp. 876–882; August 15, 1959.) Infrared radiation is used to measure the current-density /added-carrier-density characteristics. The nature of the semiconducting surface rather than the metal is the major factor controlling the contact characteristics. Two unusual classes of results are described.

537.311.33 928

Compound Semiconductors—D. A. Wright. (*Electronic Engrg.*, vol. 31, pp. 659–665; November, 1959.) After a general description of some factors influencing performance, applications of individual binary and ternary compounds are considered with reference to tabulated data on their properties. The optimum requirements for thermoelectric refrigeration are noted.

537.311.33 929

On the Study of the Semiconductor Properties of Chalcogenides of Aluminium, Gallium and Indium—E. Kauer and A. Rabenau. (*Z. Naturforsch.*, vol. 13a, pp. 531–536; July, 1958.) Optical measurements confirm that all chalcogenides of Al, Ga and In of the type $A_2^{III}B_3^{VI}$ have semiconductor properties. Band gaps and their temperature dependence are given and compared with the results of other authors.

537.311.33:061.3 930

1958 International Conference on Semiconductors—(*J. Phys. Chem. Solids*, vol. 8, pp. 1–552; January, 1959.) The text is given of papers presented at the conference held in Rochester, N.Y. August 18–22, 1958.

537.311.33:534.2–8 931

The Conductivity of Semiconductors in an Ultrasonic Field—V. A. Zhuravlev and M. I. Kozak. (*Zh. Eksp. Teor. Fiz.*, vol. 36, pp. 343–344; January, 1959.) Measurements have been made on Se, CdS, PbS, Cu_2O, SnO_2 and Ge semiconductors in a 600-kc field of intensity 10 watts/cm^2. Conductivity changes occurred in all cases and are attributed to thermal effects of the irradiation.

537.311.33:538.63 932

The Influence of the Geometry on the Transverse Magnetoresistance Effect in Rectangular Semiconductor Plates—H. J. Lippmann and F. Kuhrt. (*Z. Naturforsch.*, vol. 13a, pp. 462–474; June, 1956.) The resistance effect controlled by the geometry of the specimen is calculated for small and large Hall angles. The theoretical results obtained accord with measurements made on InSb specimens by Weiss and Welker (143 of 1955).

537.311.33:538.632 933

The Influence of the Geometry on the Hall Effect in Rectangular Semiconductor Plates—H. J. Lippman and F. Kuhrt. (*Z. Naturforsch.*, vol. 13a, pp. 474–483; June, 1958.) *See* also 932 above.

537.311.33:539.12.04 934

Temperature-Dependent Defect Production in Bombardment of Semiconductors—G. K. Wertheim. (*Phys. Rev.*, vol. 115, pp. 568–569; August 1, 1959.) The decreased defect density observed after low-temperature bombardment may be due to the production of a metastable vacancy—interstitial pair which may either anneal or form the defect. A temperature dependence in the production rate arises if these two competing processes have different activation energies.

537.311.33:546.26–1 935

Electrical Resistivity Changes Observed in a Semiconducting Diamond after Heat Treatment—R. E. Mutch and F. A. Raal. (*Nature*, vol. 184, suppl. no. 24, pp. 1857–1858; December 12, 1959.) Resistivity measurements on a diamond slab consisting of a blue and a white portion show that both portions are semiconducting to different degrees and are separated by a well-defined boundary. The reduction in donor concentration in both portions on heating appears to be consistent with a bimolecular annealing process, the white portion, with more donor centers, showing a greater change in resistivity.

531.311.33:546.28 936

Infrared Spectrum and Carrier Mobility in the Intrinsic-Conduction Range of Silicon—F. R. Kessler and J. Schnell. (*Z. Naturforsch.*, vol. 13a, pp. 458–461; June, 1958.) Measurements of conductivity and infrared absorption between 1.0 and 3.5μ were made in the temperature range 300°–1000 °K on single-crystal *i*-type Si. The carrier density obtained is in agreement with that derived from Hall-effect measurements by other authors.

537.311.33:546.28 937

Deep Energy Levels in Silicon—H. Irmler. (*Z. Naturforsch.*, vol. 13a, pp. 557–559; July, 1958.) The recombination-center and acceptor energy levels were determined from measurements on pure Si and Si specimens doped with Cu, Ag or Co.

537.311.33:546.28 938

The Control of Resistivity in Pulled Silicon Crystals—A. Trainor and P. T. Harris. (*Proc. Phys. Soc.*, vol. 74, pp. 669–670; November 1, 1959.) This is achieved by pulling with a reduced gas pressure to permit evaporation of the impurity.

537.311.33:546.28 939

Diffusion of Oxygen in Silicon—R. A. Logan and A. J. Peters. (*J. Appl. Phys.*, vol. 30, pp. 1627–1630; November, 1959.) By studying the process of the donor fomation by heat treatment in crystals of known oxygen concentration, the solubility and diffusivity of oxygen in Si in the temperature range 1250°–1400°C have been determined.

537.311.33:546.28 940

Infrared Studies of Birefringence in Silicon—S. R. Lederhandler. (*J. Appl. Phys.*, vol. 30, pp. 1631–1638; November, 1959.) Techniques are described for observing and measuring permanent and elastic strains.

537.311.33:546.289 941

Zeeman Effect on Light due to Intrinsic Recombination in Germanium—C. Benoit à la Guillaume and O. Parodi. (*J. Electronics Control*, vol. 6, pp. 356–358; April, 1959. In French.) Observations of the Zeeman effect on recombination radiation in As-doped Ge show the energy shift in a field of 40,000 oersteds to be about 4×10^{-4} ev and confirm the hypothesis that this radiation is due to exciton annihilation. See 3369 of 1959 (Gosnet, *et al.*).

537.311.33:546.289 942

Light Emission and Noise Studies of Individual Microplasmas in Silicon p-n Junctions—A. G. Chynoweth and K. G. McKay. (*J. Appl. Phys.*, vol. 30, pp. 1811–1813; November, 1959.) "At low currents in the prebreakdown region of broad-area diffused silicon p-n junctions in which the breakdown is by an avalanche mechanism, only a few light-emitting microplasmas are present. These appear in succession as the current is increased and the appearance of each spot is accompanied by its own set of characteristic microplasma current pulses. It is found also that effectively all the emitted light arises at these microplasmas and that they carry, essentially, all of the breakdown current. The light intensity of an individual microplasma is roughly proportional to the current flowing through it."

537.311.33:546.289 943

Visible Light from a Germanium Reverse-Biased p-n Junction—J. T. Nelson and J. C. Irvin. (*J. Appl. Phys.*, vol. 30, p. 1847; November, 1959.) A phenomenon similar to that observed in Si [see, *e.g.*, 3514 of 1958 (Cheynoweth and Pearson)] is described.

537.311.33:546.289 944

Observation of Direct Tunnelling in Germanium—J. V. Morgan and E. O. Kane. (*Phys. Rev. Lett.*, vol. 3, pp. 466–468; November 15, 1959.) The transition from "indirect" to "direct" tunnelling has been observed experimentally at 77°K. Calculations are compared with experimental data.

537.311.33:546.289:534.2–8 945

Temperature Dependence of Fractional Velocity Changes in a Germanium Single Crystal—F. Stein, N. G. Einspruch, and R. Truell. (*J. Appl. Phys.*, vol. 30, pp. 1756–1758; November, 1959.) Report of interferometer measurements of elastic constants for compressional-wave propagation in the frequency range 30–170 mc.

537.311.33:546.289:535.514.2–15 946

Polarization of Infrared Radiation by Reflection from Germanium Surfaces—D. F. Edwards and M. J. Bruemmer. (*J. Opt. Soc. Amer.*, vol. 49, pp. 860–861; September, 1959.) A Ge surface is an efficient infrared polarizer over a wide range of wavelengths.

537.311.33:546.289:538.63 947

Nernst and Ettingshausen Effect in Germanium between 300 and 750°K—H. Mette, W. W. Gärtner and C. Loscoe. (*Phys. Rev.*, vol. 115, pp. 537–542; August 1, 1959.) Measurements have been made between 300° and 750°K of a) the two effects in single crystals of different conductivity type and with various impurity densities, in magnetic fields of 9000 G; b) the Nernst effect of 2100 G. Results are compared with theory.

537.311.33:546.289:539.23 948

Electrical Conductivity of Amorphous Vapour-Deposited Germanium Films—L. Reimer. (*Z. Naturforsch.*, vol. 13a, pp. 536–541; July, 1958.) The temperature dependance of resistivity was measured in vacuum in the temperature range 20°–400°C. Comparisons are made with the properties of crystalline films.

537.311.33:546.48'19 949

Cyclotron Resonance in $CdAs_2$—M. J. Stevenson. (*Phys. Rev. Lett.*, vol. 3, pp. 464–466; November 15, 1959.)

537.311.33:546.682'86 950

Thermal Conductivity of Indium Antimonide at Low Temperatures—E. V. Mielczarek and H. P. R. Frederikse. (*Phys. Rev.*, vol. 115, pp. 888–891; August 15, 1959.) Umklapp, isotope and boundary scattering contributions to thermal resistivity were calculated theoretically and subtracted from the measured value of thermal resistivity. The number of point impurities subsequently deduced agrees with that given by electrical measurements.

537.311.33:546.682'86 951

The Energy-Dependence of Electron Mass in Indium Antimonide determined from Measurements of the Infrared Faraday Effect—S. D. Smith, T. S. Moss, and K. W. Taylor. (*J. Phys. Chem. Solids*, vol. 11, pp. 131–139; September, 1959.) Values of dE/dK as a function of k_F for the conduction band of InSb, where k_F is the wave vector at the Fermi surface, have been calculated from the Faraday rotation due to free electrons. Results are in agreement with the band structure calculated by Kane (3156 of 1958).

537.311.33:546.682'86 952

Plastic Deformation of InSb by Uniaxial Compression—J. J. Duga, R. K. Willardson, and A. C. Beer. (*J. Appl. Phys.*, vol. 30, pp. 1798-1803; November, 1959.) Plastic deformation by unixaial compression was found to decrease electron mobility and magnetoresistance but to have no effect on the Hall coefficient.

537.311.33:546.873'241 953

The Magnetic Susceptibility of Bismuth Telluride—R. Mansfield. (*Proc. Phys. Soc.*, vol. 74, pp. 599–603; November 1, 1959.) The susceptibility has been measured over the temperature range 100°-600°K; the magnitude of the contributions to the susceptibility from various sources is discussed.

537.311.33:548.0 954

The Effect of Pressure on Zinc Blende and Wurtzite Structures—A. L. Edwards, T. E. Slykhouse, and H. G. Drickamer. (*J. Phys. Chem. Solids*, vol. 11, pp. 140–148; September, 1959.)

537.311.33:621.382 955

Temperature Dependence and Lifetime in Semiconductor Junctions—D. A. Jenny and J. J. Wysocki. (*J. Appl. Phys.*, vol. 30, pp. pp. 1692–1698; November, 1959.) The temperature dependence of p-n-junction current can be held to a minimum over a given temperature range by using material with a minority-carrier lifetime below a certain value. Calculations applied to GaAs show that an optimum lifetime should be attainable in practice by controlled doping with recombination-center impurities. The upper operating-temperature limit of junction devices is calculated for Ge, Si, InP and GaAs.

537.311.33:621.391.822 956

Load-Dependent Noise in Oxide Semiconductors at Low Frequencies—K. Leberwurst. (*NachrTech.*, vol. 8, pp. 568–580; December, 1958.) The changes of noise characteristics with temperature and oxygen pressure are investigated for a number of sintered oxide semiconductors. From consideration of the mechanism of chemisorption a model is developed for a polycrystalline oxide semiconductor which allows for different types of noise to originate in the interior and at the boundary of unit cells making up the substance. Results of measurements are discussed with reference to an equivalent circuit based on the model.

537.312.8 957

Influence of Collective Effects on the Magnetoresistance of Metals—R. A. Coldwell-Horsfall and D. ter. Haar. (*Phys. Rev.*, vol. 115, pp. 891–893; August 15, 1959.) Two methods are used to investigate the influence of the correlations between carriers on the magnetoresistance β. The change in β in both a one-band and a two-band model is considered.

537.533 958

On the Question of Electron Emission of Nickel in the Curie Region—F. Fraunberger and A. Kellerer. (*Z. Phys.*, vol. 154, pp. 419–422; April 7, 1959.) Electron emission and, in particular, exo-electron emission of a Ni specimen was investigated to discover a possible anomaly in the Curie region. No anomaly was found.

537.533:546.431 959

Effect of Oxygen on the Work Function of Barium—P. A. Anderson and A. L. Hunt. (*Phys. Rev.*, vol. 115, pp. 550–552; August 1, 1959.) The effect is measured for various exposures to oxygen.

537.533:546.59 960

Work Function of Gold—P. A. Anderson. (*Phys. Rev.*, vol. 115, pp. 535–554; August 1, 1959.) The measured value of contact difference of potential Au-Ba is found to be 2.31 ±0.02 volts and the work function of Au 4.83±0.02 ev.

537.533:546.621 961

Electron Emission from Plastically Strained Aluminum—W. D. Von Voss and F. R. Brotzen. (*J. Appl. Phys.*, vol. 30, pp. 1639–1645; November, 1959.) An experimental investigation is made of the effect of mechanical variables on emission, both during and after straining. A model is proposed correlating these in terms of the formation of point discontinuities in the surface oxide layer and this is compared with the experimental results.

538.214:546.31 962

Magnetic Susceptibility of Alkali Elements—K. Venkateswarlu and S. Sriraman. (*Z. Naturforsch.*, vol. 13a, pp. 451–458; June, 1958. In English.)

Part 1: Sodium and Potassium (pp. 451–455).

Part 2: Liquid Alloys of Sodium and Potassium (pp. 455–458).

538.22:537.311.31 963

Magnetic Susceptibility and Electrical Resistivity of Au-Mn Alloys—A. Giansoldati, J. O. Linde, and G. Borelius. (*J. Phys. Chem., Solids*, vol. 11, pp. 46–54; September, 1959) Report of measurements on alloys containing 10–75 atomic per cent Mn.

538.221 946

The Magnetic Law of Approach in Plastically Deformed Nickel and Nickel-Cobalt Single Crystals—H. Kronmüller. (*Z. Phys.*, vol. 154, pp. 574–600; April 21, 1959.) Experimental investigation of the influence of plastic deformation at room temperature and at −183° C on the approach to ferromagnetic saturation.

538.221 965

Magnetic Viscosity in Iron due to Carbon Atoms Anchored in Dislocations—G. Biorci, A. Ferro, and G. Montalenti. (*J. Appl. Phys.*, vol. 30, pp. 1732–1735; November, 1959.)

538.221:539.234:537.312.8 966

The Determination of the Curie Temperature of Thin Films by means of the Ferromagnetic Resistance Variation—W. Hellenthal. (*Z. Naturforsch.*, vol. 13a, pp. 566–567; July, 1958.) The dependance of Curie temperature on film thickness is plotted for Ni films. See 1944 of 1959.

538.221:621.318.134 967

The Influence of the Valency States of Cations on Electrical Conductivity of Mg-Mr Ferrite—S. Krupička and Závěta. (*J. Electronics Control*, vol. 6, pp. 333–336; April, 1959.) The resistivity of iron-deficient Mg ferrite is low, owing to the presence of Fe^{2+} ions, but can be greatly increased by the addition of Mn. This is attributed to the formation of stable Mn^{4+}-Fe^{2+} pairs, preventing the Fe^{2+} ions taking part in the conduction process.

538.221:621.318.134 968

Evidence for Triangular Moment Arrangements in MO. Mn_2O_3—I. S. Jacobs. (*J. Phys. Chem. Solids*, vol. 11, pp. 1–11; September, 1959.) A consequence of the triangular arrangement of moments suggested by Yafet and Kittel (3414 of 1952) is that at field strengths higher than those required for ferrimagnetic domain alignment, there should be a linear increase in net magnetization with field. Measurements on several spinel-type compounds show this differential susceptibility.

538.221:621.318.134 969

The Magnetocrystalline Anisotropy of Cobalt-Substituted Manganese Ferrite—R. F. Pearson. (*Proc. Phys. Soc.*, vol. 74, pp. 505–512; November 1, 1959.) The anisotropy due to Co ions in Mr ferrite varies linearly with Co concentration up to 25 per cent; the variation is not as great as in magnetite or as would be expected from Co ferrite values.

538.221:621.318.134 970

Paramagnetic Resonance of Yb^{3+} in Yttrium Gallium Garnet—D. Boakes, G. Garton, D. Ryan, and W. P. Wolf. (*Proc. Phys. Soc.*, vol. 74, pp. 663–665; November 1, 1959.)

538.221:621.318.134 971

Magnetic Properties of Rare Earth Ions in Garnets—W. P. Wolf. (*Proc. Phys. Soc.*, vol. 74, pp. 665–667; November 1, 1959.) *See* also 970 above.

538.221:621.318.134:538.566 972

Faraday Effect in Various Small Ferrite Rods—F. Picherit. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 69–70; July 6, 1959.) The polarimetric analyzer described in 3574 of 1958 has been applied to the study of the Faraday effect in 4B ferrite rods of diameter down to 1.6 mm.

538.221:621.318.134:538.569.4 973

Magnetic Resonance of Ferrites at the Compensation Temperature—J. Paulevé. (*Ann. Télécommun.*, vol. 13, pp. 311–324; November/December, 1958. and vol. 14, pp. 2–20; January/February, 1959.) A study of ferrimagnetic resonance theory at temperatures below the Curie point supported by measurements on Li chrome ferrites and Gd and Er garnets. 43 references.

538.221:621.318.134:538.569.4 974

The Influence of Conducting Surfaces on the Gyromagnetic Resonance of Ferrite Bodies—W. Haken. (*Arch. elekt. Übertragung*, vol. 12, pp. 562–566; December, 1958.) The calculation of demagnetizing factors by magnetostatic methods must be modified if conducting surfaces are present. Using a mirror-image principle the demagnetizing factors are calculated for magnetized ferrite strips in rectangular waveguides; measurement results confirm the analysis.

538.222:538.569.4 975

Optical Detection of Paramagnetic Resonance Saturation in Ruby—I. Wieder. (*Phys. Rev. Lett.*, vol. 3, pp. 468–470; November 15, 1959.) Description of experimental measurements.

538.632:546.87:539.23 976

Hall Effect of Bismuth Films Condensed by Quenching—W. Buckel. (*Z. Phys.*, vol. 154, pp. 474–485; April 7, 1959.)

538.652 977

Measurement of the Linear Magnetostriction of Hard-Worked Nickel—H. E. Stauss. (*J. Appl. Phys.*, vol. 30, pp. 1648–1650; November, 1959.)

539.2:539.12.04 978

The Effects of Nuclear Radiation on Materials—T. P. Flanagan. (*J. Electronics Control*, vol. 6, pp. 337–346; April, 1959.) The effects of gamma and neutron radiation are described. Magnetic materials and thermocouples are included.

621.315.612.015.5 979

Dielectric Breakdown of Porous Ceramics—R. Gerson and T. C. Marshall. (*J. Appl. Phys.*, vol. 30, pp. 1650–1653; November, 1959.) The measured dielectric strength in porous materials is a function of porosity, void size, and of the dimensions of the test specimen.

621.315.615.015.5 980

Conduction Currents in Liquid *n*-Hexane under Microsecond Pulse Conditions—A. H. Sharbaugh and P. K. Watson. (*Nature*, vol. 184, suppl. no. 26, pp. 2006–2007; December 26, 1959.) No evidence for electron multiplication was obtained at fields below 1.25 mv/cm. At fields in the vicinity of breakdown, large values of current density were measured which may lead to local vaporization and the formation of bubbles with subsequent breakdown of the liquid dielectric.

621.315.616.9:621.3.048 981

An Alternative Method for Comparing the Electrical Properties of Epoxy Casting Resins—D. A. Thompson. (*Electronic Engrg.*, vol. 31, pp. 686–687; November, 1959.)

669.21/.22:621.382.3.032.27 982

Investigations on some Noble-Metal Alloys used in Semiconductor Techniques—K. Müller and W. Merl. (*Elektrotech. Z., Edn A*, vol. 80, pp. 515–518; August 1, 1959.) Physical and mechanical properties are tabulated of various alloys of Ag and Au with group-III and group-V elements suitable as contact materials for semiconductor devices, and curves of specific resistance as a function of alloy composition are given.

MEASUREMENTS AND TEST GEAR

529.786+621.3.018.41 (083.7) 983

The Determination of Time and Frequency—(*Tech. Mitt. PTT*, vol. 37, pp. 1–32; January 1, 1959.) The text is given of the following papers presented at a meeting of the Swiss national committee of URSI at Neuchâtel, 1958.

a) **The Scientific Importance of Atomic Frequency Standards**—J. Rossel (pp. 2–6. In French).

b) **The Atomic Clocks**—J. Bonanomi (pp. 6–9).

c) **The Technique of the Atomic Determination of Frequency and Time**—J. De Prins and P. Kartaschoff (pp. 10–14).

d) **Problems of Astronomic Time**—J. P. Blaser, and W. Schuler (pp. 14–17. In French).

e) **Time Signals and Standard Frequencies**—C. Wyser (pp. 18–23. In French).

f) **The Time Service of the Swiss Post, Telegraph and Telephone Administration**—K. J. Bohren (pp. 23–32).

529.786+621.3.018.41(083.74) 984

An Improved Caesium Resonance Frequency and Time Standard—L. Essen and J. V. L. Parry. (*Nature*, vol. 184, suppl. no. 23, p. 1791; December 5, 1959.) Preliminary measurements show that a precision of a few parts in 10 inches is practicable. See 204 of 1958.

621.317.331.029.6 985

Measurement of Microwave Resistivity by Eddy-Current Loss in Spheres—T. Kohane and M. H. Sirvetz. (*Rev. Sci. Instr.*, vol. 30, pp. 1059–1060; November, 1959.) Applies to materials in which "skin effect" is appreciable in samples of ordinary size.

621.317.36:621.374.32 986

Digital Rate Synthesis for Frequency Measurement and Control—T. J. Rey. (Proc. IRE, vol. 47, pp. 2106–2112; December, 1959.) The signal whose period is to be measured is in the form of a pulse train of constant repetition rate. This train is compared with the average repetition rate of a series of nonuniformly spaced pulses from a standard source, the differences being used for frequency indication, or in a feedback loop for control purposes.

621.317.373:621.374.4 987

A Phase Multiplier—E. Augustin. (*Hochfrequenz.*, vol. 67, pp. 84–87; November. 1958.) Frequency multiplication and mixing are used in the equipment described to obtain a ten- or hundred-fold increase of very small phase angles at 10 kc. Phase multiplication by a factor of 1000 may be achieved using a carefully designed circuit and highly stable supplies.

621.317.412 988

Application of a Weakly Inhomogeneous Magnetic Field to the Quantitative Determination of Small Ferromagnetic Admixtures in Susceptibility Measurements— D. Gerstenberg. (*Z. Metallk.*, vol. 50, pp. 472–477; August, 1959.) Ferromagnetic content of 10^{-8} gram in a specimen can be determined with the apparatus described.

621.317.412 989

Absolute Measurement of Magnetic Susceptibility by a Quasistatic Induction Method—M. C. Mesnage, P. Grivet and M. Sauzade. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 59–60; July 6, 1959.) Changes in induction when a hollow cylinder placed in the gap of a permanent magnet is filled with a liquid or a gas are observed by a null method. Results of observations on O_2 and NO are given.

621.317.742 990

VSWR Indicators with Automatic Read-Out—M. Kollanyi and R. M. Verran. (*Electronic Engrg.*, vol. 31, pp. 666–671; November, 1959.) A probe carriage is moved along a slotted line to produce stored values of the maximum and minimum detected signals. Different methods of obtaining a direct reading of the amplitude ratio of these signals are described with circuit details.

621.317.75:534.44 991

Method of Obtaining Amplitude and Phase Spectra of a Transient Function using Graphical Input Data—W. J. Remillard. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 531–534; April, 1959.) A method of harmonic analysis is describe using commercial equipment in conjunction with switching, adding and triangular-wave shaping circuits.

621.317.77:621.373 992

A System for Providing a Precise Vector Voltage—D. J. Collins and J. E. Smith. (*Electronic Engrg.*, vol. 31, pp. 684–685; November, 1959.) Schematic details are given of a means of producing, from a reference oscillator source, signals of any desired amplitude and phase.

OTHER APPLICATIONS OF RADIO AND ELECTRONICS

551.510.62:621.372.413 993

A Microwave Refractometer—R. Schünemann and W. Steffen. (*Hochfrequenz.*, vol. 67, pp. 78–83; November, 1958.) A cavity-resonator-type refractometer operating at 9.4 kmc is described and some initial measurements near the ground are discussed.

621–52:621.318.57:621.387 994

Cold-Cathode Tube Circuits—H. Liebendörfer. (*Electronic Radio Eng.*, vol. 36, pp. 436–442; December, 1959.) Describes briefly various basic control circuits using cold-cathode triodes and their application in systems for lighting control, flame detection in oil-fired boilers, thread-break detectors, etc.

621–52:621.318.57:621.387 995

ACCESS—a Static Switching System using Cold-Cathode Tubes—R. W. Brierley. (*Electronic Engrg.*, vol. 31, pp. 646–654; November, 1959.) A description of some features of an automatic production control system developed by the Austin Motor Co.

621–57:537.228.4 996

Flame-Sprayed Ceramic Dielectric for Transducers—G. V. Planner and A. Foster. (*J. Brit. IRE*, vol. 19, pp. 699–702; November, 1959.) "A high-speed electromechanical transducer system based on the Johnson-Rahbek effect is described, in which a flame-sprayed ceramic of high permittivity replaces the conventional semiconductor."

621.363 997

Thermomagnetic Generator—J. F. Elliott. (*J. Appl. Phys.*, vol. 30, pp. 1774–1777; November, 1959.) Calculations are given for a practical thermal-energy converter using gadolinium. Energy is extracted from heat sources near 20°C; reasonable efficiency and power output are claimed. See 1309 of 1949 (Brillouin and Iskenderian).

621.383.4:535–15:621.397.331.2 998

Electronic Scanning System for Infrared Imaging—M. E. Lasser, P. H. Cholet, and R. B. Emmons. (Proc. IRE, vol. 47, pp. 2069–2075; December, 1959.) An infrared image is focused on a semiconducting window of silicon at one end of a tapered tube. This is scanned by an electron beam creating free carriers locally in the semiconductor and producing a moving opaque spot which absorbs energy as the image passes through the tube to an infrared detector. The detector output is fed to a television-type monitor for display.

621.384.622.21 999

Longitudinal Movement of Electrons and Tolerances in a Linear Accelerator—A. D. Vlasov. (*Radiotekh. Elektron.*, vol. 4, pp. 295–302; February, 1959.) Determination of the injection conditions governing the acceleration and the compactness of the energy spectrum of accelerated particles.

621.385.833 1000

The Construction of Four-Pole Magnetic Lenses without Iron—A. Septier and G. Chartier. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 64–66; July 6, 1959.) A theoretical investigation of the magnetic field due to four-pole linear and sheet currents has been applied to the design of a strong-focusing magnetic lens which has been constructed and found to give satisfactory results.

621.387.4:621.374.3 1001

Fast Neutron Time-of-Flight Spectrometer—G. C. Neilson, W. K. Dawson, and F. A. Johnson. (*Rev. Sci. Instr.*, vol. 30, pp. 963–975; November, 1959.) A detailed description is given of a neutron spectrometer incorporating a simple time/pulse-height converter suitable for use in the mμs region. Either RF beam deflection or the gamma coincidence method is used to provide zero time indication.

621.56:537.322.1 1002

Thermoelectric Cooling—(*Electronic Engrg.*, vol. 31, pp. 690–692; November, 1959.) Refrigeration figures-of-merit of thermocouple elements are shown to be greater for certain semiconductors than for metals. Practical applications of thermoelectric cooling are discussed.

PROPAGATION OF WAVES

621.391.812.62 1003

Correlation of Meteorological Phenomena with Propagation beyond the Horizon over the Mediterranean—L. Bonavoglia. (*Alta Frequenza*, vol. 27, pp. 815–824; December, 1958.) Results of propagation tests between Sardinia and Minorca (see also 2229 of 1958) and of meteorological measurements are compared.

621.391.812.62 1004

Path Antenna Gain in an Exponential Atmosphere—W. J. Hartman and R. E. Wilkerson. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 273–286; November/December, 1959.) This extension of previous estimates of the loss in gain caused by tropospheric or stratospheric scattering includes the effect of an exponential model atmosphere and a scattering cross section inversely proportional to the fifth power of the scattering angle. Assuming isotropic turbulence the loss is about 2-db less than Staras' estimate (235 of 1959), which ignored the exponential atmosphere. The loss would be further reduced if anisotropic turbulence were included.

621.391.812.621 1005

Effect of Atmospheric Horizontal Inhomogeneity upon Ray Tracing—B. R. Bean and B. A. Cahoon. (*J. Res. Nat. Bur. Stand.*, vol. 63D, pp. 287–292; November/December, 1959.) The effect is negligible above 1 km. Below this, rays at elevation angles less than about 2° are sensitive to extreme horizontal inhomogeneities, as in ducting conditions. The method is partly graphical and unjustifiable for routine correction of ray paths.

621.391.812.621 1006

Partial Reflections in the Atmosphere and Long-Distance Propagation: Parts 1 and 2—F. du Castel, P. Misme, and J. Voge. (*Ann. Télécommun.*, vol. 13, pp. 209–214 and pp. 265–270; July/August and September/October, 1958.) Refractive-index measurements show the existence in the atmosphere of small layers (feuillets) each with a refractive index different from that of the mean surrounding value. Interpretation of the results suggests that the atmosphere may be considered as a dielectric medium composed of such layers which may be stable or unstable and identifiable by the slope of the index gradient through the layer.

621.391.812.63 1007

A Discussion of Ionospheric Demodulation Near Gyro-Frequency—G. L. Goodwin. (*Aust. J. Phys.*, vol. 12, pp. 157–163; June, 1959.) The effect occurs at a height of about 90 km and does not appear to decrease at dawn. A wave reflected from the F-layer is demodulated by unequal amounts during its two passages through the region. The results cannot be explained by the theory of wave interaction.

621.391.812.8 1008

Comparison of the Long-Term Prediction Methods of C.R.P.L. and S.P.I.M.—P. Halley, D. Lepechinsky and P. Mouchez. (*Ann. Télécommun.*, vol. 13, pp. 254–264; September/October, 1958.)

RECEPTION

621.391.812.3:621.317.6.087.4 1009

Correlation between Fading Signals—J. Bell. (*Electronic Tech.*, vol. 37, pp. 36–40; January, 1960.) An instrument is described for the determination of the correlation coefficient between two positive rectified fading signals using a sum-and-difference method.

621.391.821:621.3.087.4 1010

Recording of the Mean Square Value of Atmosphereic Noise—F. Carbenay. (*Compt. rend. Acad. Sci., Paris*, vol. 249, pp. 67–68; July 6, 1959.) The method used at the CNET is described. A vertical omnidirectional antenna above a metal earth is used and the square of the intensity of the linearly amplified current at a given frequency is measured by three thermocouples of different sensitivity each associated with a galvanometer. Recordings may be made photographically.

STATIONS AND COMMUNICATION SYSTEMS

621.391 1011

Poisson, Shannon, and the Radio Amateur—J. P. Costas. (Proc. IRE, vol. 47, pp. 2058–2068; December, 1959.) From a statistical analysis of the problem of communicating in a congested band of frequencies, it is concluded that reducing the required bandwidth for a service, in the hope of acquiring an exclusive channel does not always offer the best prospect of intelligible reception. The use of wider bandwidths is advocated, particularly for amateur work where specific frequencies are not allocated for individual transmitters, and for military situations in which considerable interference, unintentional or deliberate, may be expected.

621.391 1012

Error-Correcting Codes—a Linear Programming Approach—E. J. McCluskey, Jr. (*Bell Syst. Tech. J.*, vol. 38, pp. 1485–1512; November, 1959.) Theorems are given for the matrices used to construct systematic error-correcting codes and are proved for minimum-redundancy codes.

621.391:534.75 1013

Indices of Signal Detectability Obtained with Various Psychophysical Procedures—J. A. Swets. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 511–513; April, 1959.) See also 3854 of 1959 (Tanner and Birdsall).

621.391:534.78 1014

Communication Efficiency of Vocoders—A. R. Billings. (*Electronic Radio Eng.*, vol. 36, pp. 449–453; December, 1959.) A vocoder, in which speech is modulated and a single sideband passed to the analyzer filters through an amplitude limiter, is shown on comparison with the convention vocoder to have a greater communication efficiency, this being defined as the ratio of the actual rate of information to the rate of transmission in an ideal system subject to the same restrictions.

621.391:621.376.5 1015

Ideal Binary Pulse Transmission by A.M and F.M.—E. D. Sunde. (*Bell Syst. Tech. J.*, vol. 38, pp. 1357–1426; November, 1959.) Intersymbol interference can be avoided in binary pulse transmission by FM without the need for a wider channel bandwidth than in DSB AM for equal pulse transmission rates. Explici general expressions are derived for the appropriate shaping of the band-pass channel. Th optimum division of channel shaping between transmitting and receiving filters for FM and AM with random noise, and the relation between error probability and signal/noise rati are discussed.

621.391.822 1016

Transition Probability Densities of the Smoothed Random Telegraph Signal—W. M. Wonham. (*J. Electronics Control*, vol. 6, pp. 376–384; April, 1959.) An extension of earlier analysis (3634 of 1958) to derive the transition probability functions of the associated Markov process.

621.395:621.372 1017

The South Lancashire Radiophone Service—(*Brit. Commun. Electronics*, vol. 6, pp. 858–861; December, 1959.)

Part 1—The General System—L. T. Arman (pp. 858–860). A VHF mobile radio service provides communication between land mobile stations and the public telephone network.

Part 2—The Radio-Telephone Equipment—B. Armstrong (pp. 860–861). A discussion of the technical specification.

621.395:621.376.56 1018

A Delta Modulation System using Junction Transistors—B. E. Williams. (*Electronic Engrg.* vol. 31, pp. 674–680; November, 1959.) A speech link operating at a digit frequency of 14 kc uses alternating binary encoding—a form in which the signal has no dc component—and requires less bandwidth than normal binary code.

621.395.665.1:534.861 1019

Contribution on the Reciprocal Control of Dynamic Range—H. Völz. (*Hochfrequenz.*, vol. 67, pp. 87–94; November, 1958.) Six-terminal networks are introduced in this theoretical consideration of dynamic compression and restitution of the original dynamics after the signal has passed through a noisy communication channel. Practical systems designed to avoid the occurrence of transients are discussed.

621.396.65 1020

Convention on Radio Links—(*Alta Frequenza*, vol. 27, pp. 578–832; December, 1958.) Third issue covering the proceedings of a convention held in Rome, June 5–8, 1957. Second issue: 2014 of 1959. Abstracts of some of the papers are given individually; titles of others are as follows:

a) **Microwave Amplification by Earthed-Grid Triodes**—G. B. Stracca (pp. 578–614).

b) **Applications of Ferrites in Microwave Radio Links**—M. Vadnjal (pp. 615–628).

c) **Frequency Control of Klystrons by Reference Cavity**—L. Del Bello (pp. 629–633).

d) **On the Improvement of Linearity of Reflex Klystrons used as Frequency-Modulated Oscillators**—G. Cicconi (pp. 634–682.)

e) **New Components for Miniaturized Microwave Radio Links**—M. Mueller (Müller) (pp. 683–698. In English).

f) **Problems of Automatic Switching**—A. Ricagni (pp. 699–715).

g) **Criteria and Measurements of Suitability of Equipment for Radio Links**—G. Monti-Guarnieri (pp. 716–751).

h) **A 6000-Mc/s Communication System for 300 Telephone Channels**—E. Viti (pp. 752–778).

i) **Multiplex for Three High-Quality Music Channels**—A. Pasini (pp. 779–789).

j) **Directive Aerials with Dual Polarization**—G. Parmeggiani (pp. 794–814).

621.396.74.029.51/.53(43) 1021

Long and Medium-Wave Transmitters in the German Federal Republic—(*Rundfunktech. Mitt.*, vol. 2, pp. 304–307; December, 1958.) *See* also 1023 below.

621.396.74.029.55(43) 1022

Short-Wave Frequencies in the German Federal Republic—(*Rundfunktech. Mitt.*, vol. 2, p. 303; December, 1958.)

621.396.74.029.62(43) 1023

List of VHF Transmitters in the German Federal Republic—(*Rundfunktech. Mitt.*, vol. 2, pp. 300–303; December, 1958.) The lists and map of transmitter locations give the position as of November 1, 1958.

621.396.931 1024

Radio Telephony in French Express Trains—[*Engineer* (*London*), vol. 208, pp. 158–159; August 28, 1959.)] On the route Paris-Lille a VHF link operating at 160 mc is provided between trains and a chain of 11 lineside stations with a cable connection to a Paris exchange.

SUBSIDIARY APPARATUS

621.3.087.4:621.396.96 1025

Electronic Line-Storage Device for the Compression of the Frequency Band of Periodically Recurring Signals, particularly of Radar Displays—K. Lange. (*Nachrichtentech. Z.*, vol. 11, pp. 619–627; December, 1958.) The operation of a CR -tube line-storage system is discussed. Equipment is described for measuring the integrating characteristics of such storage devices. See also 3744 of 1956 (Meinke and Groll).

621.316.722.027.5:621.385.4 1026

A Small, High-Voltage, Regulated Power Supply with Variable Output—J. D. O'Toole. (*Electronic Engr.*, vol. 31, pp. 681–683; November, 1959.) The design of a regulating circuit operating in the range 1–4kv is described which uses a beam tetrode as a series regulator and two double triodes in the feedback circuit.

621.316.722.073.3:621.385.032.213 1027

A Transistorized L. T. Regulator—J. H. Deichen. (*Electronic Engr.*, vol. 31, pp. 688–689; November, 1959.) "The methods of providing a stabilized dc supply for tube heaters are examined and their limitations are discussed. A simple circuit using a transistor and two Zener diodes is then given and its design and performance described."

TELEVISION AND PHOTOTELEGRAPHY

621.397:621.391.8.029.63 1028

Some Aspects of Television Reception on Band V—H. N. Gant. (*J. Brit. IRE*, vol. 19, pp. 727–733; November, 1959.) Band-V television receiver design problems are considered with regard to available components. Suitable antenna systems and their performance figures are noted.

621.397.132.001.4:621.317.755 1029

A Vectorscope Unit—K. G. Freeman. (*Electronic Engrg.*, vol. 31, pp. 655–658; November, 1959.) Circuit details are given of an instrument which uses the principles of coherent detection to provide a vectorial display of NTSC subcarrier chrominance signals.

621.397.232.2:621.391.82 1030

Co-channel Television Interference and its Reduction—E. W. Chapin, L. C. Middlekamp, and W. K. Roberts. (IRE TRANS. ON BROADCAST TRANSMISSION SYSTEMS, vol. PGBTS-10, pp. 3–24; June, 1958. Abstract, PROC. IRE, vol. 46, p. 1665; September, 1958.)

621.397.232.2 :621.391.82 1031

Reduction of Co-channel Television Interference by Very Precise Offset Carrier Frequency—L. C. Middlekamp. (IRE TRANS. ON BROADCAST TRANSMISSION SYSTEMS, vol. PGBTS-12, pp. 5–10; December, 1958.) The effect on picture degradation of frequency-offset variation is investigated, and the improvement in picture quality to be gained by using precise offset values held to a close tolerance is discussed.

621.397.232.2:621.391.82 1032

Investigation of the Operation of Television Transmitters with Precise Offset-Carrier Frequencies—H. Hopf. (*Rundfunktech. Mitt.*, vol. 2, pp. 265–276; December, 1958.) The reduction of the transmitter-frequency tolerance to about ±2.5 cps results in an improvement by more than 10 db in the RF protection ratio (*see* also 1030 above). Curves of protection ratios are plotted for various types of carrier-offset and include a set of curves of recommended ratios for the 625-line CCIR system, with a reference-interference ratio of 30 db for carrier offset equal to $\frac{2}{3}\times$ line frequency.

621.397.334 1033

A New Approach to Kinescope Beam Convergence—J. W. Schwartz and P. E. Kaus. (IRE TRANS. ON ELECTRON. DEVICES, vol. ED-5, pp. 275–282; October, 1958. Abstract, PROC. IRE, vol. 47, p. 495; March, 1959.)

621.397.334:621.374.33 1034

A Gating Circuit for Single-Gun Colour Television Tubes.—K. G. Freeman. (*J. Brit. IRE*, vol. 19, pp. 667–677; November, 1959.) Gating circuits and their limitations are discussed. A new gating circuit is described, which employs low-leve gating of the red, green and blue video signals in conjunction with a wide-band amplifier.

621.397.6.001.4 1035

Laboratory Television Transmitter for the Intermediate-Frequency Range—P. Klopf. (*Rundfunktech. Mitt.*, vol. 2, pp. 253–264; December, 1958.) A modulator unit is described for use in tests on residual-sideband transmission for the 625-line CCIR system. The quality of transmission via the modulator and a standard IF receiver is examined.

621.397.61:535.88 1036

Further Development of the Television Episcope—R. Theile and F. Pilz. (*Rundfunktech. Mitt.*, vol. 2, pp. 290–292; December, 1958.) Details are given of an improved version of the equipment described in 1374 of 1959.

621.397.7—182.3 1037

A Contribution to the Design and Construction of Television Outside-Broadcast and Film-Recording Vehicles—G. Schadwinkel and H. Käding. (*Rundfunktech. Mitt.*, vol. 2, pp. 277–289; December, 1958.) Vehicles developed by the West German radio organizations and their equipment are described.

621.397.72 1038

Some Aspects of the Design of a Small Television Station—A. Harris. (*J. Brit. IRE*, vol. 19, pp. 705–721; November, 1959.) "Some of the factors governing the choice of equipment for use in small commercial television stations in isolated areas are discussed. Specific reference is made to two different types of installation at station ZBM-TV, Bermuda, using the same basic equipment."

621.397.74(43) 1039

The Television Network of the German Federal Republic—(*Rundfunktech. Mitt.*, vol. 2, pp. 293–299; December, 1958.) Tabulated data on television transmitters as of November 1, 1958, with maps showing their location and that of television links.

621.397.743 1040

Climatic Resistance, Operational Reliability, and Emergency Circuitry of Television Frequency Translators—K. Fischer, H. J. Fraisse, and W. Marks. (*Telefunken Ztg.* vol. 32, pp. 47–58, March, 1959. English summary, pp. 73–74.) The effects of outdoor operation on unattended television relay equipment are discussed. Means of minimizing these effects and of ensuring the maintenance of services are illustrated by examples of specially designed units.

TRANSMISSION

621.396.61:621.372.51 1041
Gauging Transmitters to Overcome Jamming—P. W. Esten. (*Electronics*, vol. 32, pp. 68–70; November 27, 1959.) A combining network enables four transmitters to feed a common antenna to increase radiated power.

621.396.61:621.391.82 1042
Interference Area of a Transmitter for Tropospheric-Scatter Radio Links—A. Chinni (*Alta Frequenza*, vol. 27, pp. 825–832; December, 1958.) A nomogram has been constructed for obtaining the distance from a transmitter at which the interference field intensity exceeds a certain level for 0.1 per cent of the time, for any given frequency, radiated power, antenna gain and radiation pattern.

TUBES AND THERMIONICS

621.382.2 1043
Zener Diodes—their Properties and Applications—J. M. Waddell and D. R. Coleman. (*Wireless World*, vol. 66, pp. 17–21; January, 1960.)

621.382.2:621.391.822 1044
The Noise of Diodes—W. Drechsel. (*NachrTech.*, vol. 8, pp. 538–541; December, 1958.) Fundamental causes of LF and HF noise in semiconductor diodes are considered and the choice of diode characteristics for optimum performance in static, dynamic, and mixer operation is discussed.

621.382.2/.3:539.12.04 1045
How Radiation Affects Semiconductor Devices—M. F. Wolff. (*Electronics*, vol. 32, pp. 55–57; November 27, 1959.) Transistor and diode damage and the change in circuit characteristics due to radiation effects are noted. Radiation-resistant devices such as the thin-base Ge transistor and the tunnel diode are mentioned.

621.382.23 1046
The Tunnel Diode—Circuits and Applications—I. A. Lesk, N. Holonyak, Jr. and U. S. Davidsohn. (*Electronics*, vol. 32, pp. 60–64; November 27, 1959.) Details are given of the characteristics of tunnel diodes possessing a high negative conductance and a high resistance to nuclear-radiation and temperature effects. Their applications in amplifier, oscillator and detector circuits are illustrated.

621.382.23:621.372.44 1047
Surface-Dependent Losses in Variable-Reactance Diodes—D. E. Sawyer. (*J. Appl. Phys.*, vol. 30, pp. 1689–1691; November, 1959.) High-frequency performance is lowered by these losses which cause the series equivalent resistance to be larger than the integrated bulk resistance. The effect is shown to vary with surrounding atmosphere and an explanatory model is given.

621.382.3:621.391.822 1048
The Noise Equivalent Circuit of the Transistor—G. Winkler. (*NachrTech.*, vol. 8, pp. 542–548; December, 1958.) The representation of transistor noise in the form of an equivalent noise three-pole network using noise parameter measurements or by an equivalent circuit based on calculation is described.

621.382.3.012.6 1049
Transistor Matching Impedances—A. G. Bogle. (*Electronic Tech.*, vol. 37, pp. 28–30; January, 1960.) Calculations are described relating the variation of input impedance, output impedance and gain of a Type-OC 71 transistor to changes of operating point and negative feedback.

621.382.3.032.27 1050
Application of a Photogravure Process to the Deposition of Metal Contacts on Semiconductors—P. Michelet and J. Vareine. (*Onde élect.*, vol. 39, pp. 858–862; November, 1959.) A photosensitive synthetic resin is used in the process which is applied to HF Si transistors. Reference is made to the elimination of the superficial oxide layer by the process.

621.382.333 1051
An 85-Watt-Dissipation Silicon Power Transistor—R. W. Aldrich, R. H. Lanzl, D. E. Maxwell, J. O. Percival, and M. Waldner. (IRE Trans. on Electron Devices, vol. ED-5, pp. 211–215; October, 1958. Abstract, Proc. IRE, vol. 47, p. 494; March, 1959.)

621.382.333 1052
Large-Signal Rise Times in Junction Transistors—W. W. Gärtner. (IRE Trans. on Electron Devices, vol. ED-5, p. 316; October, 1958.) An investigation of collector current response using a more exact expression for α_N than that used by Moll (885 of 1955) yields considerably higher values for the large-signal rise times.

621.382.333 1053
The Physical Interpretation of Measurements on Transistors—F. J. Hyde (*J. Electronics Control*, vol. 6, pp. 362–364; April, 1959.) The equation for the effective lifetime of holes in the base given by Deb and Daw (2043 of 1959) is shown to be not generally valid, and a modified equation is derived.

621.382.333:621.317.3 1054
Measurement of the High-Frequency Base Resistance and Collector Capacitance of Drift Transistors—F. J. Hyde and T. E. Price. (*J. Electronics Control*, vol. 6, pp. 347–355; April, 1959.) A modified Turner circuit (354 of 1955) is used to determine $r_{bb'}$ and c_c separately. The effect of stray emitter-collector capacitance on the measurements is analyzed.

621.382.333:621.318.57 1055
Two-Terminal Asymmetrical and Symmetrical Silicon Negative-Resistance Switches—R. W. Aldrich and N. Holonyak, Jr. (*J. Appl. Phys.*, vol. 30, pp. 1819–1824; November, 1959.) "By making use of an emitter region shorted by a metallic contact to an adjacent base region, a new form of *p-n-p-n* switch is obtained. Several new structures are described, including a symmetrical (or ac) switch. Typical experimental results on switches which break down in the range from 25 to 40 volts are presented."

621.382.333.33 1056
A Silicon *p-n-p-n* Power Triode—K. Kawana and T. Misawa. (*J. Electronics Control*, vol. 6, pp. 324–332; April, 1959.) A simplified theory assuming equal ionization for electrons and holes is presented which explains the controlling effect of base current on the *I/V* characteristics of the triode. Characteristics of a developmental triode are given.

621.382.333.4 1057
The Emitter Tetrode—R. A. Gudmundsen. (IRE Trans. on Electron Devices, vol. ED-5, pp. 223–225; October, 1958. Abstract, Proc. IRE, vol. 47, p. 495; March, 1959.)

621.383.4 1058
The Limiting Sensitivity and the Noise Spectrum of Germanium Junction Photodiodes—L. Ya. Pervova. (*Radiotekh. Elektron.*, vol. 4, pp. 330–334; February, 1959.) The sensitivity threshold was of the order of 10^{-10} lumen second $^{1/2}$ with a light-beam modulation frequency 70 cps. The noise spectrum in the range 0.5 cps to several hundres of cps obeys the $1/f$ law; for higher frequencies the noise is close to the shot noise of the photodiode dark current.

621.385 (083.72) 1059
Vacuum Diodes and Grid-Controlled Vacuum Tubes: Terminology—(*Nachrichtentech. Z.*, vol. 11, pp. 635–644; December, 1958.) A list of 138 terms and their definitions recommended by the Nachrichtentechnische Gesselschaft; the corresponding English and French terms are given in most cases. This is an amended version of 652 of 1958.

621.385.1:621.391.822 1060
Flicker Noise of Valves in the L.F. Region—H. Mutschke. (*NachrTech.*, vol. 8, pp. 585–590; December, 1958.) The mechanism of flicker noise is discussed with reference to previous work [*e.g.*, 1284 of 1957 (Lindemann and van der Ziel)] and results are given of tests on various types of tubes to determine the dependence of flicker noise on heater voltage, anode current and running time.

621.385.3.029.63 1061
PC86, a Newly Developed Grounded-Grid Triode for Decimetre Waves (U.H.F.)—H. Bünger. (*Telefunken Ztg.*, vol. 31, pp.262–265; December, 1958. English summary, p. 274.) The glass tube described is designed for operation at frequencies up to 800 mc; its amplification factor is 68, and its slope 14 ma/volt.

621.385.6 1062
Periodic Electrostatic Focusing of a Hollow Electron Beam—C. C. Johnson. (IRE Trans. on Electron Devices, vol. ED-5, pp. 233–243; Abstract, Proc. IRE, vol. 47, p. 495; March, 1959.)

621.385.6 1063
A Symmetry Property of Space-Charge Waves in Accelerated Electron Beams—I. P. Shkarofsky. (IRE Trans. on Electron Devices, vol. ED-5, pp. 283–288; October, 1958. Abstract, Proc. IRE, vol. 47, p. 495; March, 1959.)

621.385.6 1064
On Speed Charge Waves—R. H. C. Newton. (*J. Electronics Control*, vol. 6, pp. 321–323; April, 1959.) Comment on 2058 of 1959 (Trevena).

621.385.6 1065
Calculation of Electron-Beam Divergence at Medium Gas Pressures—B. H. Wadia. (*J. Electronics Control*, vol. 6, pp. 307–320; April, 1959.) A method is described involving step-by-step integration, by which the beam profiles in the presence of gas at $10^{-5}-10^{-7}$ mm Hg can be estimated. Universal curves are given which enable the designer to estimate the modification of the "perfect-vacuum" behavior ($<10^{-8}$ mm Hg) to be expected in practical tubes.

621.385.6:621.375.9 1066
The Kinetic Power Theorem for Parametric, Longitudinal, Electron-Beam Amplifiers—H. A. Haus. (IRE Trans on Electron Devices, vol. ED-5, pp. 225–232; October, 1958. Abstract, Proc. IRE, vol. 47, p. 495; March, 1949.)

621.385.6:621.391.822 1067
New Method of Measuring the Noise Parameters of an Electron Beam—S. Saito. (IRE Trans. on Electron Devices, vol. ED-5, pp. 264–275; October, 1958. Abstract. Proc. IRE, vol. 47, p. 495; March, 1959.)

621.385.62 1068
A Multicavity Klystron with Double-Tuned

Output Circuit—H. J. Curnow and L. E. S. Mathias. (*Proc. IEE*, pt. B, vol. 106, pp. 487–488; September, 1959. Discussion, pp. 492–494.) An improved bandwidth (5.3 per cent–6.3 per cent for 2.5-mw output) has been obtained from a 6-cavity pulsed S-band klystron amplifier by the use of a double-tuned output circuit.

621.385.62:621.376.32 1069

A Simple Investigation of the Cross-Modulation Distortion arising from the Pulling Effect in a Freqency-Modulated Klystron—D. T. Gjessing. (*Proc. IEE*, pt. B, vol. 106, pp. 473–477; September, 1959. Discussion, pp. 492–494.) An expression for the distortion spectrum is derived theoretically, and families of curves showing severity of distortion are plotted. It is shown that small mis-matches of the output feeder give serious crosstalk.

621.385.624 1070

Large-Signal Analysis of the Multicavity Klystron—S. E. Webber. (IRE TRANS ON ELECTRON DEVICES, vol. ED-5, pp. 306–315; October, 1958. Abstract, PROC. IRE, vol. 47, p. 496; March, 1959.)

621.385.63 1071

Space and Time Harmonics in Electron Streams—R. Müller, (*Arch. elekt. Übertragung*, vol. 12, pp. 527–532; December, 1958.) Wave propagation is analyzed in systems with space-periodic structure which changes with time. These conditions arise when a high-intensity traveling wave interacts with an electron beam; harmonic frequencies are then generated. See also 2962 of 1957.

621.385.63 1072

General Design Procedure for High-Efficiency Travelling-Wave Amplifiers—J. E. Rowe and H. Sobol. (IRE TRANS. ON ELECTRON DEVICES, vol. ED-5, pp. 288–300; October, 1958. Abstract, PROC. IRE, vol. 47, p. 495; March, 1959.)

621.385.63 1073

Design and Performance of Coupled-Helix Transducers for Travelling-Wave Tubes—T. S. Chen. (*J. Electronics Control*, vol. 6, pp. 289–306; April, 1959). Discussion of systems in which coupling between a traveling-wave-tube helix and the input or output coaxial cable is achieved by connecting the inner of the cable to a short helix wound round the outside of the main helix. The choice of pitch for the coupling helix is discussed and experimental results are given.

621.385.63 1074

Approximate Analytic Expressions for TWT Propagation Constants—W. H. Louisell. (IRE TRANS ON ELECTRON DEVICES, vol. ED-5, pp. 257–259; October, 1958. Abstract. PROC. IRE, vol. 4, p. 495; March, 1959.)

621.385.63 1075

Travelling-Wave-Tube Propagation Constants for Finite Values of Gain per Wavelength—D. A. Dunn, G. S. Kino, and G. W. C. Mathers. (IRE TRANS. ON ELECTRON DEVICES, vol. ED-5, pp. 243–251; October, 1958. Abstract, PROC. IRE, vol. 47, p. 495; March, 1959.)

621.385.63 1076

Improvement of Travelling-Wave-Tube Efficiency through Collector Potential Depression—F. Sterzer. (IRE TRANS. ON ELECTRON DEVICES, vol. ED-5, pp. 300–305; October, 1958. Abstract. PROC. IRE, vol. 47, pp. 495–496; March, 1959.)

621.385.63 1077

Theory and Behaviour of Helix Structures for a High-Power Pulsed Travelling-Wave Tube—G. W. Buckely and J. Gunson. (*Proc. IEE*, pt. B, vol. 106, pp. 478–486; September, 1959. Discussion, pp. 492–494.) A multistart helix structure which may be water-cooled is considered theoretically and experimentally. There is reasonable agreement between measurements on 4- and 8-start structures and calculations of impedance and phase velocity on equivalent bounded sheath helices.

621.385.63 1078

Traveling-Wave-Tube Analogue—G. D. Sims and I. M. Stephenson. (*Electronic Tech.*, vol. 37, pp. 20–24, January, 1960.) The properties of any traveling-wave tube whose structure possesses equivalent parameters can be simulated, regardless of its actual physical form, by using the lumped-circuit principle and designing the inductance drift-tube structure to provide a given impedance and phase shift. The model described was designed primarily to investigate forward-wave interaction.

621.385.633 1079

Velocity and Current Distributions in the Spent Beam of the Backward-Wave Oscillator—J. W. Gewartowski. (IRE TRANS. ON ELECTRON DEVICES, vol. ED-5, pp. 215–222; October, 1958. Abstract, PROC. IRE, vol. 47, pp. 494–495; March, 1959.)

621.385.633.1 1080

Influence of Magnetic Focusing Fields and Transverse Electron Motion on Starting Conditions for Spurious Oscillations in O-Type Backward-Wave Oscillators—H. G. Kosmahl. (IRE TRANS. ON ELECTRON DEVICES, vol. ED-5, pp. 252–257; October, 1958, Abstract, PROC. IRE, vol. 47, p. 495; March, 1959.

621.385.69:621.372.2 1081

A New Wide-Band Thermionic Valve—T. Kojima. (*Onde élect.*, vol. 39, pp. 876–833; November, 1959.) Theoretical and practical considerations in the design of a distributed-amplifier-type tube are discussed [see 902 of 1954 (Lewis)]. Results obtained with a prototype tube operating from low frequencies up to 70 mc are compared with theoretical calculations.

621.387:621.362 1082

"Open-Circuit" Voltages in the Plasma Thermocouple—H. W. Lewis and J. R. Reitz. (*J. Appl. Phys.*, vol. 30, pp. 1838–1839; November, 1959.) Further discussion of the plasma diode (366 of January) clarifying the mechanism involved.

MISCELLANEOUS

621.38/.39:061.3 1083

Annual Convention of the Popov Society in Moscow, 12th–17th May, 1958—F. H. Lange. (*NachrTech.*, vol. 8, pp. 591–592; December, 1958.) A brief report on some of the papers presented at the convention, and a complete list of titles and authors covering the following four of twelve sections: a) information theory, b) antenna installations, c) semiconductor and miniature circuit elements, and d) electronics.

Translations of Russian Technical Literature

Listed below is information on Russian technical literature in electronics and allied fields which is available in the U. S. in the English language. Further inquiries should be directed to the sources listed. In addition, general information on translation programs in the U. S. may be obtained from the Office of Science Information Service, National Science Foundation, Washington 25, D. C., and from the Office of Technical Services, U. S. Department of Commerce, Washington 25, D. C.

On Adaptive Control Processes, *R. Bellman and R. Kalaba* 1
A Dynamic Programming Approach to Adaptive Control Processes, *M. Freimer* 10
On the Optimum Synthesis of Multipole Control Systems in the Wiener Sense, *H. C. Hsieh and C. T. Leondes* 16
On Adaptive Control Systems, *L. Braun, Jr.* 30
Extension of Phase Plane Analysis to Quantized Systems, *P. H. Ellis* 43
Simplified Method of Determining Transient Response from Frequency Response of Linear Networks and Systems, *V. S. Levadi* 55
A New Method of Analysis of Sampled-Data Systems, *A. Papoulis* 67
Statistical Filter Theory for Time-Varying Systems, *E. C. Stewart and G. L. Smith* 74
On the Phase Plane Analysis of Nonlinear Time-Varying Systems, *R. F. Whitbeck* 80
On the Use of Growing Harmonic Exponentials to Identify Static Nonlinear Operators, *H. J. Lory, D. C. Lai, and W. H. Huggins* 91
A Parameter Tracking Servo for Adaptive Control Systems, *M. Margolis and C. T. Leondes* 100
Maximum Effort Control for Oscillatory Element, *H. K. Knudsen* 112
Identification and Command Problems in Adaptive Systems, *E. Mishkin and R. A. Haddad* 121
Evaluating Residues and Coefficients of High Order Poles, *D. Hazony and J. Riley* 132
Coherent Optical Data Processing, *L. J. Cutrona, E. N. Leith, and L. J. Porcello* 137
Pole Determinations with Complex-Zero Inputs, *J. A. Brussolo* 150
Random Noise with Bias Signals in Nonlinear Devices, *G. S. Axelby* 167
Nongyroscopic Inertial Reference, *J. J. Klein* 182
Sampled Data Design by Log Gain Diagrams, *M. P. Pastel and G. J. Thaler* 192

Vol. AC-4, No. 3, December, 1959

Preface 1
Officers, Technical Program Committees and Session Chairmen 2
Fundamental Theory of Automatic Linear Feedback Control Systems, *I. M. Horowitz* 5
General Approach to Control Theory Based on the Methods of Lyapunov (Abstract), *R. E. Kalman and J. E. Bertram* 20
The Impact of Information Conversion on Control, *H. Chestnut and W. Mikelson* 21
Controlled Propulsion, *K. K. Dannenberg* 30

Attitude Control of Space Vehicles (Abstract), *C. R. Gates* 34
Tracking and Path Control (Abstract), *R. C. Booton, Jr.* 35
Control of the Human Environment (Abstract), *P. Webb* 36
Signal Stabilization of Self-Oscillating Systems (Abstract), *R. Oldenburger and T. Nakada* 37
A Root-Locus Method for the Analysis of Nonlinear Servomechanisms, *M. J. Abzug* 38
Some Nonlinear Control Techniques Novel to Control Engineers Employed by a Biological Control System (Abstract), *M. Clynes* 45
On the Analysis of Bi-Stable Control Systems, *B. E. Amsler and R. E. Gorozdos* 46
Effect of Power Source Regulation on the Response of a Control System Amplifier (Abstract), *R. J. Kochenburger* 59
Pendulous Velocity Meter Control Synthesis, *S. G. Shutt and S. A. White* 60
The Analysis of Demodulating Compensating Networks, *G. J. Murphy and J. F. Egan* 71
Mathematical Models for Computer Control Systems (Abstract), *T. M. Stout* 80
Multi-Loop Automatic Temperature Control System Design for Fluid Dynamics Facility Having Several Long Transport Delays, *G. J. Fiedler and J. J. Landy* 81
Some Linear and Nonlinear Aspects of Hot Gas Servo Design, *R. V. Halstenberg* 97
Topological Techniques for the Solution of Multi-Loop Sampled Systems (Abstract), *R. Ash, W. H. Kim and G. M. Kranc* 108
Synthesis of Third Order Contactor Control Systems (Abstract), *I. Flugge-Lotz* 109
On the General Theory of Control Systems (Abstract), *R. E. Kalman* 110
On Optimal Computer Control (Abstract), *J. E. Bertram and P. E. Sarachik* 111
Control System Analysis and Design Via the Second Method of Lyapunov: (I) Continuous-Time Systems, (II) Discrete Time Systems (Abstract), *R. E. Kalman and J. E. Bertram* 11
Adaptive Flight Control (Abstract), *O. H. Schuck* 11
Electronic Solid-State Automatic Flight Control Systems (Introduction to Papers A, B and C) 11
Electronic Gain Control in Automatic Flight Control Systems (Paper A), *W. Henn and E. L. Boronow* 11
Electronic Memory in Automatic Flight Control Systems (Paper B), *D. H. Blauvelt and A. S. Robinson* 12
Pulse Controlled Integration in Automatic Flight Control Systems (Paper C), *A. S. Robinson* 13
Reaction Wheel Attitude Control for Space Vehicles, *R. W. Froelich and H. Patapoff* 13
D-Decomposition Analysis of Automatic Control Systems *B. W. Lanzkron and T. S. Higgins* 15
Optimization of the Adaptive Function by the Z-Transform Method (Abstract), *S. S. L. Chang* 17
Application of Pole-Zero Concepts to Design of Sampled-Data Systems, *D. P. Lindorff* 17
Synthesis of Feedback Systems with Specified Open-Loop and Closed-Loop Poles and Zeros, *W. E. Carpenter* 18
Calculating Zeros of Functions Arising in Various Control System Problems (Abstract), *W. R. Evans* 19
Random Sampling: Its Effect on Spectral Density (Abstract), *A. R. Bergen* 19
Spectral Characterization of Control System Nonlinearities, *R. B. McGhee* 19
Techniques for the Optimum Synthesis of Multiple Control Systems with Random Processes as Inputs, *H. C. Hsieh and C. T. Leondes* 21
Predictor-Rely Servos with Random Inputs, *T. R. Benedict* 23

Broadcast and Television Receivers

Vol. BTR-5, No. 1, January 1959

The Art of Getting Along 1
Professional Group on Broadcast and Television Receivers Administrative Committee 2
Minutes of Administrative Committee Meeting, October 28, 1958 3
A New AGC Circuit, *F. J. Banovic and R. Miller* 5
The Fuse in the Horizontal-Deflection System, *W. Feingold* 10
Application of RCA Drift Transistors to FM Receivers, *J. W. Englund and H. Thanos* 13
Television IF Selectivity and Adjacent-Channel Interference, *T. Matzek* 18
The Optimum Impedance and Noise Figures of Television Input Tubes with Various Circuits, *L. E. Matthews* 22
Television Receiver Color Decoder Design, *D. Richman* 27
Detection of Asymmetric Sideband Signals in the Presence of Noise, *T. Murakami and R. W. Sonnenfeldt* 46
Television Wireless Remote Control, *R. Muniz* 76

Vol. BTR-5, No. 2, May, 1959

Meet Our New 1959 Chairman i
Professional Group on Broadcast and Television Receivers ii
Minutes of Administrative Committee Meeting, March 25, 1959 .. 1
Chapter News 4
Awards 5
Design of Transistor Vertical Deflection Output and Driver Stages, *M. J. Hellstrom* 7
Improving Vertrical Synchronization, *H. W. Proudfoot* 18
Double-Tuned Transistor IF Amplifiers for TU Receivers, *H. C. Lee* 25
Hold Range and Pulse Interference Immunity of Triggered Deflection Oscillators for Television Receivers, *E. Luedicke* 33
Modification of U. S. Television Receivers for Operation in 50-Cycle Power Areas, *R. C. Auriema and R. J. Farber* 5
Simplification of Viewer Brightness and Contrast Controls on Color TV Receivers, *L. L. Burns, R. W. Ahrons, and L. B. Johnston* ... 5

Vol. BTR-5, No. 3, December, 1959

Circuit Theory

Vol. CT-6, No. 1, March, 1959

Abstracts 2
Buyer's Guide, *D. A. Huffman* 4
Transition Matrices of Sequential Machines, *S. Seshu, R. E. Miller, and G. Metze* 5
Hazards and Delays in Asynchronous Sequential Switching Circuits, *S. H. Unger* 12
A Note on Memory Aspects of Sequence Transducers, *J. M. Simon* 26
Equivalent Sequential Circuits, *W. J. Cadden* 30
Analysis of Bilateral Iterative Networks, *F. C. Hennie* 35
The Theory of Autonomous Linear Sequential Networks, *B. Elspas* 45
Linear Modular Sequential Circuits, *B. Friedland* 61
Linear Multivalued Sequential Coding Networks, *J. Hartmanis* 69
Equivalent Ladder Networks by the Use of Signal Flow Graphs, *C. F. Simone* 75
Identification of Certain Networks with Reflection Coefficient Zero Locations, *D. C. Fielder* 81
The Degrees of Freedom in *RLC* Networks, *A. Bers* 91
Pole Migration in Coupled-Resonator Filters, *R. La Rosa* 95
Bounded Real Scattering Matrices and the Foundations of Linear Passive Network Theory, *D. Youla, L. Castriota, and H. J. Carlin* 102
A New Operation for Analyzing Series-Parallel Networks, *K. E. Erickson* 124

Reviews of Current Literature

Abstracts of Articles on Circuit Theory 127

Correspondence

Flatness and Symmetric Low-Pass Lossless Filters, *P. R. Geffe* 129
Comments on "A Necessary and Sufficient Condition for a Bounded Nondecreasing Step Response," *A. Papoulis, A. H. Zemanian, M. R. Aaron and R. G. Segers* 129
A Sensitivity Theorem, *F. F. Kuo* 131
Stochastic Combinational Relay Switching Circuits and Reliability, *A. A. Mullin* 131
A Synthesis Procedure Based on Linvill's RC Active Structure, *J. B. Cruz, Jr.* 133
On a Determinant Relating to Cascaded Circuits, *H. L. Armstrong* 134
Topological Network Analysis as a Computer Program, *E. W. Hobbs and F. J. MacWilliams* 135
Reducing Computation Time in the Analysis of Networks by Digital Computer, *W. Mayeda* 136
On the Response to Unit Step of Highly Cascaded Butterworth Filters, *B. L. Hicks and R. Stemmler* 137
PGCT News 139

Vol. CT-6, Special Supplement, May, 1959

Nonstationary Smoothing and Prediction Using Network Theory Concepts, *S. Darlington* 1
A New Kind of Matched Filter, *H. P. Debart* 14
Nonlinear System Characterization and Optimization, *A. G. Bose* 30
Canonical Forms for Information-Lossless Finite-State Logical Machines, *D. A. Huffman* 41
Group Code Equivalence and Optimum Codes, *A. B. Fontaine and W. W. Peterson* 60
Multi-Error Correcting Codes for a Binary Asymmetric Channel, *W. H. Kim and V. Freiman* 71
A Class of Binary Systematic Codes Correcting Errors Occurring at Random and in Bursts, *L. Calabi and H. G. Haefeli* 79
Graph Theory and Electric Networks, *F. Harary* 95
How to Grow Your Own Trees from Cut-Set or Tie-Set Matrices, *E. A. Guillemin* 110
Applications of Matrix Algebra to Network Theory, *I. Cederbaum* 127
Reliability of a Physical System, *H. Mine* 138
The Theory of Switching Nets, *M. Yoeli* 152
Irredundant and Redundant Boolean Branch-Networks, *L. Löfgren* 158
On the Classification of Boolean Functions, *S. W. Golomb* 176
A Limit of Crosspoint Numbers, *N. Ikeno* 187
The Representation of Signals, *R. M. Lerner* 197
Some Results on Noise Through Circuits, *W. M. Brown* 217
The Probability Density of the Output of a Filter When the Input is a Random Telegraphic Signal: Differential-Equation Method, *J. A. McFadden* 228
A Comparison of Random and Periodic Data Sampling for the Detection of Signals in Noise, *D. Middleton* 234
On the Mean Square Stability of Random Linear Systems, *J. C. Samuels* 248
Stability of Circuits with Randomly Time-Varying Parameters, *J. E. Bertram and P. E. Sarachik* 260
Functional Equations in Adaptive Processes and Random Transmission, *R. Bellman and R. Kalaba* 271
On Passive One-Way Systems, *H. Gamo* 283

Vol. CT-6, No. 2, June, 1959

Abstracts 142
Application of Routh's Algorithm to Network-Theory Problems, *W. D. Fryer* 144
On the Optimum Performance of Variable and Nonreciprocal Networks, *T. Schaug-Pettersen and A. Tonning* 150
Correction to "Numerical Determination of Cascaded LC Network Elements from Return Loss Coefficients," *D. C. Fielder* 158
A Power Theorem on Absolutely Stable Two-Ports, *G. E. Sharpe, J. L. Smith, and J. R. W. Smith* 159
Time-Response Characteristics of a System as Determined by its Transfer Function, *J. D. Brule* 163
Flow-Graph Solutions of Linear Algebraic Equations, *C. L. Coates* 170
Triode Network Topology, *A. W. Keen* 188
Application of Mellin and Hankel Transforms to Networks with Time-Varying Parameters, *F. R. Gerardi* 197
Image Parameter Square-Frequency Filter Design, *D. B. Pike* 208
Maximally-Flat Time Delay Ladders, *S. Deutsch* 214
On Realizability of a Circuit Matrix, *R. B. Ash and W. H. Kim* 219
Theoretical Limitations on the Gain-Bandwidth Product of Three-Terminal Networks, *J. J. Spilker, Jr.* 221

Reviews of Current Literature

Abstracts of Articles on Circuit Theory 229

Correspondence

Matrix Analysis of RL and RC Oscillators, *A. J. Cote, Jr.* 232

Electron Devices

Vol. ED-6, No. 1, January, 1959

On Calculating the Current Gain of Junction Transistors with Arbitrary Doping, *H. L. Armstrong* 1
Traveling-Wave Tube Efficiency Degradation Due to Power Absorbed in an Attenuator, *C. K. Birdsall and C. C. Johnson* 6
A Class of Waveguide-Coupled Slow-Wave Structures, *J. Feinstein and R. J. Collier* 9
A Gun and Focusing System for Crossed-Field Traveling-Wave Tubes, *O. L. Hoch and D. A. Watkins* 18
Germanium *P-N-P-N* Switches, *I. A. Lesk* 28
Large-Signal Theory of UHF Power Triodes, *A. D. Sutherland* 35
The Design and Characteristics of a Megawatt Space-Harmonic Traveling-Wave Tube, *M. Chodorow, E. J. Nalos, S. P. Otsuka, and R. H. Pantell* 48
The Effect of Space Charge on Bunching in a Two-Cavity Klystron, *T. G. Mihran* 54
A Microwave Electron Velocity Spectrograph, *P. B. Wilson and E. L. Ginzton* 64
Independent Space Variables for Small-Signal Electron Beam Analyses, *D. L. Bobroff* 68
Effect of Transient Voltages on Transistors, *H. C. Lin and W. F. Jordan, Jr.* 79
The Germanium Microwave Crystal Rectifier, *A. C. MacPherson* 83
Transient Analysis of Junction Transistors, *W. F. Gariano* 90
Electron-Beam Flow in Superimposed Periodic and Uniform Magnetic Fields, *J. R. Anderson* 101
Strapped Bifilar Helices for High-Peak-Power Traveling-Wave Tubes, *D. A. Watkins and D. G. Dow* 106
Dispenser Cathode Magnetrons, *G. A. Espersen* 115
Correction to "Ultrasensitive Techniques Employing the Helium Leak Detector," *J. L. Lineweaver* 118
Experimental Notes and Techniques
Method for Determining Specific Cooling Rates of Plate Materials in Vacuum, *C. W. Horsting, I. S. Solet, T. A. Sternberg, and P. Avakian* 119
Contributors 120

Vol. ED-6, No. 2, April, 1959

Frequency Characteristics of Semiconductor Rectifier at Voltages Greater than kT/q, *L. Depian, W. E. Newell, and A. G. Milnes* 125
A Lumped Model Analysis of Noise in Semiconductor Devices, *R. N. Beatie* 133
A Physical Theory of Junction Transistors in the Collector-Voltage-Saturation Region, *C. Huang* 141
Surface and Geometry Effects on Large Signal Base Input Voltage and Input Resistance of Junction Transistors, *C. Huang, C. M. Chang and M. Weissenstern* 154
On the Theory of DC Amplification Factor of Junction Transistors, *S. Wang and T. T. Wu* 162
An Alloy-Diffuse Silicon High Current Transistor With Fast Switching Possibilities, *D. Navon and P. De Beurs* 169

High-Level Transistor Operation and Transport Capacitance, *K. E. Mortenson* 174
Impedance and Dispersion Characteristics of the Flattened Helix, *C. C. Johnson* 189
An Investigation and Application of the Contrawound Helix, *J. E. Nevins* 195
Bibliography on Electroluminescence and Related Topics, *H. F. Ivey* 203
The Variable-Capacitance Parametric Amplifier, *E. D. Reed* 216
Propagation of Space-Charge Waves in Diodes and Drift Spaces, *H. G. Kosmahl* 225
Disturbances in a Multi-Velocity Plasma, *J. R. Pierce and J. A. Morrison* 231
A Self-Excited Drift Tube Klystron Frequency Multiplier for Use in Generating Millimeter Waves, *W. H. Cornetet, Jr.* 236

Experimental Notes and Techniques.

A High-Frequency Alpha Cutoff Jig, *L. M. Terman* 242
Magnetron Cathode Arm Radiation and Luminescence, *R. A. White and A. Bamford* 242
Program of 1958 Electron Devices Meeting, October 30–31, Washington, D. C. 243
Contributors 254

Vol. ED-6, No. 3, July, 1959

Electron Beams in Axially-Symmetric Crossed Fields, *J. A. Bradshaw* 257
Laminar Flow in Magnetically-Focused Cylindrical Electron Beams, *J. L. Palmer* 262
Point-Contact Diodes in Terms of *p-n* Junction Theory, *R. E. Nelson* 270
The Nesistor—A Semiconductor Negative Resistance Device, *R. G. Pohl* 278
Super-Radiation and Super-Regneration, *C. Greifinger and G. Birnbaum* 288
A Low Potential Collector Employing an Asymmetrical Electrode in an Axially-Symmetric Magnetic Field, *D. A. Dunn, W. R. Luebke, and G. Wada* 294
Electrostatic Optics for Camera Tubes, *R. W. Redington, G. A. Saum, and P. J. van Heerden* 297
Thermally-Induced Cracking in the Fabrication of Semiconductor Devices, *T. C. Taylor* 299
Medium Power High-Speed Germanium Alloy Transistors, *H. E. Hughes, T. R. Robillard, and R. W. Westberg* 311
New Methods for the Measurement of Cathode Interface Impedance, *H. B. Frost* 315
Maximum Rapidly-Switchable Power Density in Junction Triodes, *J. M. Early* 322
On the Periodic Coupling of Propagating Structures, *N. Rynn* 325
Some Reactive Effects in Forward Biased Junctions, *T. E. Firle and O. E. Hayes* 330
The Effects of Electrode Resistance in Electroluminsecent Cells, *H. F. Ivey* 335
Semiconductor Diode Amplifiers and Pulse Modulators, *W. Ko and F. E. Brammer* 341
A Design Theory for the High-Frequency *p-n* Junction Variable Capacitor, *C. J. Spector* 347
The Radio-Frequency Current Distribution in Brillouin Flow, *M. Chodorow and L. T. Zitelli* 352

Experimental Notes and Techniques

Technique for Making Crack-Free Alloyed Junctions in Silicon, *T. C. Taylor* 358
Contributors 360

Vol. ED-6, No. 4, October, 1959

Large Signal Bunching of Electron Beams by Standing-Wave and Traveling-Wave Systems, *S. E. Webber* 365
A Theoretical Study of Ion Plasma Oscillations, *W. W. Peterson and H. Puthoff* 372
A New Electronic Gun for Picture Display with Low Drive Signals, *K. Schlesinger* 377
Diffused Silicon Nonlinear Capacitors, *A. E. Bakanowski, N. G. Cranna, and A. Uhlir, Jr.* 384
The Design and Performance of Grid-Controlled, High-Perveance Electron Guns, *H. E. Gallagher* 390
The Effects of Initial Electron Velocities and Space Charge in Secondary Emission, *M. D. Hare* 397
Space-Charge Layer Width in Diffused Junctions, *R. M. Scarlett* 405
Electron Beam Characteristics in Radially Varying Periodic Magnetic Fields, *C. C. Johnson* 409
The Effect of Secondary and Backscattered Electrons in the Parallel-Plane Diode, *L. A. Harris* 413
Theory of the Amplitron, *G. E. Dombrowski* 419
Low-Noise Klystron Amplifiers, *R. G. Rockwell* 428
The Effect of Beam Cross-Sectional Velocity Variation on Backward-Wave-Oscillator Starting Current, *N. C. Chang, A. W. Shaw, and D. A. Watkins* 437
The Cylindrical Field Effect Transistor, *H. A. R. Wegener* 442
Small-Signal Theory of Multicavity Klystrons, *G. R. White* 449
Cross Modulation and Nonlinear Distortion in RF Transistor Amplifiers, *M. Akgun and M. J. O. Strutt* 457

Experimental Notes and Techniques

Magnetron Cathode Arm Radiation and Luminescence—Sequel, *R. A. White, A. Bamford, and D. C. Buck* 468
Plasma Frequency Reduction in Electron Streams by Helices and Drift Tubes, *C. K. Birdsall and F. M. Schumacher* 468
Contributors 470
Annual Index, 1959 *Follows page* 472

Electronic Computers

Vol. EC-8, No. 1, March, 1959

The Chairman's Column 1
Absolute Minimal Expressions of Boolean Functions, *S. Abhyankar* 3
A Generalized Resistor-Transistor Logic Circuit and Some Applications, *S. C. Chao* 8
A Synthesis Technique for Minimal State Sequential Machines, *S. Ginsburg* 13
A Ring Model for the Study of Multiplication for Complement Codes, *H. L. Garner* 25
A High-Speed Analog to Digital Converter, *D. Savitt* 31
A Non-Real-Time Simulation of SAGE Tracking and BOMARC Guidance, *D. W. Ladd and E. W. Wolf* 36
Time Multiplexing as Applied to Analog Computation, *E. Rawdin* 42
A Figure of Merit for Single-Pass Data Recording Systems, *J. H. Mulligan, Jr.* 48
Simulation to Obtain a Systems Measure of an Air Duel Environment, *A. A. B. Pritsker, R. C. Van Buskirk, and J. K. Wetherbee* 55
1958 PGEC Membership Survey Report, *K. W. Uncapher* 60

Industrial Electronics

PGIE-8, January, 1959

Message from the Publications Chairman 1
A Numerically Controlled Manufacturing System, *F. E. Booth* 2
A High-Speed Low-Level Scanner, *K. Enslein* 17
Pulse-Time Positioning Used for Safety Control of High-Speed Tester, *M. E. Fitch* 25
A Positioning Servo for Automatic Machine Tool Operation, *F. H. London* 31
Automatic Packaging of Gelatin Capsules, *S. H. McMillan* 34
A Nuclear Reactor Control System, *D. J. Niehaus, R. R. Hoge, and A. B. Van Rennes* 38
Multichannel Swept Sonic Tester for Casting Quality Control, *N. W. Schubring and J. E. Stevens* 46
Management Views Automation, *I. Travis* 59

PGIE-9, April, 1959

Design of High-Performance Instrument Servos for General Purpose Computation, *K. V. Bailey and M. A. Ziniuk* 1
Electronics in Automatic Mail Cancelling and Facing, *P. W. Barnhart* 14
An Automatically Controlled Vertical Turret Lathe, *A. O. Fitzner* 19
Minimizing Production Costs Through Modular Automatic Test Equipment, *J. Tampico and H. B. Rose* 29
Data or Information, *E. A. Keller* 35

PGIE-10, July, 1959

Message from the Publications Chairman 1
Introduction to Session on Frontiers in Industrial Electronics, *C. G. Suits* 2
Automation Trends in the Banking Industry, *F. B. Miller* ......
Data-Gathering in Continuous Chemical Processing, *P. D. Schnelle* 8
Application of Data-Logging and Programming Techniques to Steel Mill Processes, *R. W. Barnitz and G. E. Terwilliger* 2
Application of Numerical Control for Automatic Manufacturing in General Industry, *W. E. Brainard* 3
The First Yugoslav Machine Tool with Digital Control, *G. L. Lukatela* 4
Design Considerations for an Automatic Rearview Mirror, *G. Platzer and L. Gau* 4
Roster of PGIE Members Listed by IRE Regions and Sections, as of June 19, 1959 4

PGIE-11, December, 1959

New Developments in Stream Analysis, *V. H. Adams and D. J. Fraade* ......
Nuclear Magnetic Resonance Applications, *H. Rubin* ......
Use of Infrared Techniques in Industrial Instrumentation, *H. L. Berman and F. G. Warnke* 1
Nondestructive Eddy Current Testing, *G. O. McClurg* 2
Electronic Photography, *M. L. Sugarman, Jr., M. B. Levine, and N. P. Steiner* 2
Applying Military Reliability Research to Industrial Electronics, *H. L. Wuerffel* 3
Digital Control Systems—Present and Future, *M. Phister, Jr.* 4
New Magnetic Recording Techniques for Data Processing, *M. E. Anderson* 4
Some Aspects of Magnetic Recording Useful for Industrial Control, *E. G. Wildanger* 5
Recent Developments in Transducer Technology, *Y. T. Li* 5

Information Theory

Vol. IT-5, No. 1, March, 1959

Frontispiece, *J. L. Doob* 2
Editorial, *J. L. Doob* 3
Correlation and Delay Line Attenuation, *M. L. Jacobson* 4
On the First Probability of Detection by a Radar Receiver System, *W. M. Stone, R. L. Brock, and K. J. Hammerle* 9
Full Decodable Code-Word Sets, *M. P. Schützenberger and R. S. Marcus* 12
On a Property of Wiener Filters, *M. Zakai* 15
Machine Recognition of Hand-Sent Morse Code, *B. Gold* 17
The Morse Distribution, *M. Freimer, B. Gold, and A. L. Tritter* 25
Correspondence
Two Properties of Pseudo-Random Sequences, *L. L. Campbell* 32
An Inequality Concerning the Envelope of a Correlation Function, *P. R. Karr* 33
Lossless Symbol Coding with Nonprimes, *J. Cocke* 33
A Comment on a Comment on Pattern Redundancy, *M. C. Paull* 34
Contributors 35

Vol. IT-5, Special Supplement, May, 1959

Nonstationary Smoothing and Prediction Using Network Theory Concepts, *S. Darlington* 1
A New Kind of Matched Filter, *H. P. Debart* 14
Nonlinear System Characterization and Optimization, *A. G. Bose* 30
Canonical Forms for Information-Lossless Finite-State Logical Machines, *D. A. Huffman* 41
Group Code Equivalence and Optimum Codes, *A. B. Fontaine and W. W. Peterson* 60
Multi-Error Correcting Codes for a Binary Asymmetric Channel, *W. H. Kim and C. V. Freiman* 71
A Class of Binary Systematic Codes Correcting Errors Occurring at Random and in Bursts, *L. Calabi and H. G. Haefeli* 79
Graph Theory and Electric Networks, *F. Harary* 9
How to Grow Your Own Trees from Cut-Set or Tie-Set Matrices, *E. A. Guillemin* 11
Applications of Matrix Algebra to Network Theory, *I. Cederbaum* 12
Reliability of a Physical System, *H. Mine* 13
The Theory of Switching Nets, *M. Yoeli* 15
Irredundant and Redundant Boolean Branch-Networks, *L. Löfgren* 15
On the Classification of Boolean Functions, *S. W. Golomb* 17
A Limit of Crosspoint Number, *N. Ikeno* 18
The Representation of Signals, *R. M. Lerner* 19
Some Results on Noise Through Circuits, *W. M. Brown* 21
The Probability Density of the Output of a Filter when the Input is a Random Telegraphic Signal: Differential-Equation Method, *J. A. McFadden* 22
A Comparison of Random and Periodic Data Sampling for the Detection of Signals in Noise, *D. Middleton* 23
On the Mean Square Stability of Random Linear Systems, *J. C. Samuels* 24
Stability of Circuits with Randomly Time-Varying Parameters, *J. E. Bertram and P. E. Sarachik* 26
Functional Equations in Adaptive Processes and Random Transmission, *R. Bellman and R. Kalaba* 27
On Passive One-Way Systems, *H. Gamo* 28

Vol. IT-5, No. 2, June, 1959

Frontispiece, *R. Price* 3
The Search for Truth (Editorial), *R. Price* 3
Experimental Results in Sequential Detection, *H. Blasbalg* 4
Minimum-Scan Pattern Recognition, *A. Gill* 5
On the Mean-Square Noise Power of an Optimum Linear Digital Filter for Correlated Noise Input, *M. Blum* 5
Single Error-Correcting Codes for Asymmetric Binary Channels, *W. H. Kim and C. V. Freiman* 6

Optimal Filtering of Periodic Pulse-Modulated Time Series, *W. A. Janos* 67
The Second-Order Distribution of Integrated Shot Noise, *J. Keilson and N. D. Mermin* 75
A Theorem on Cross Correlation Between Noisy Channels, *J. Keilson, N. D. Mermin, and P. Bello* 77
Signal-to-Noise Ratios in Smooth Limiters, *J. Galejs* 79
A Note on the Estimation of Signal Waveform, *D. Middleton* 86
Correspondence
Cumulative Distribution Functions for a Sinusoid Plus Gaussian Noise, *A. Levine and R. B. McGhee* 90
On the Characteristics of Error-Correcting Codes, *R. Chien* 91
Contributors 93

Vol. IT-5, No. 3, September, 1959

Frontispiece, *D. Gabor* 96
Editorial, *D. Gabor* 97
Note on Unique Decipherability, *E. T. Jaynes* 98
On the Use of Laguerre Polynomials in Treating the Envelope and Phase Components of Narrow-Band Gaussian Noise, *I. S. Reed* 102
Interchannel Correlation in a Bank of Parallel Filters, *J. Galejs and W. M. Cowan* 106
Application of Modular Sequential Circuits to Single Error-Correcting *P*-Nary Codes, *T. E. Stern and B. Friedland* 114
Some Spectral Properties of Weighed Random Noise, *H. S. Shapiro and R. A. Silverman* 123
Extremal Coding for Speech Transmission, *M. V. Mathews* 129
Correspondence
On Periodicity of States in Linear Modular Sequential Circuits, *B. Friedland and T. E. Stern* 136
Poincaré Metric Reliability of Switching Components, *A. A. Mullin* 137
Optimal Properties in the Statistical Theory of Reception, *H. Lass and R. M. Stewart* 138
Two Notes on a Markoff Envelope Process, *C. W. Helstrom and C. T. Isley* 139
A Note of Angle Modulation by a Mixture of a Periodic Function and Noise, *P. R. Karr* 140
Contributors 144

Vol. IT-5, No. 4, December, 1959

Frontispiece, *P. Elias* 148
Editorial, *P. Elias* 149
A Class of Systematic Codes for Non-Independent Errors, *N. M. Abramson* 150
A Probabilistic Model for Run-Length Coding of Pictures, *J. Capon* 157
A Note on Invariant Relations for Ambiguity and Distance Functions, *C. A. Stutt* 164
On Upper Bounds for Error Detecting and Error Correcting Codes of Finite Length, *N. Wax* 168
The Probability Density of the Output of an RC Filter when the Input is a Binary Random Process, *J. A. McFadden* 174
Correspondence
Direction of Change with Refinement for Unweighted and Weighted Information-Entropy Functionals, *R. Leipnik* 184
Angle Modulation by a Combination of a Periodic Function and Noise, *P. R. Karr* 186
Further Comments on "A Markoff Envelope Process," *J. N. Pierce and C. T. Isley* 186
Contributors 191
Annual Index, 1959 *Follows page* 193

Instrumentation

Vol. I-8, No. 1, March, 1959

Abstracts 2
A High-Speed Low-Level Scanner, *K. Enslein* 3
Aperture Corrective Systems, *J. Otterman* 8
Application of Quasi-Peak Detector to the Measurement of Probability Density Function, *K. Ya'coub* 19
Relative Voltmeter for "VHF/UHF Signal Generator Attenuator Calibration," *B. O. Weinschel, G. U. Sorger, and A. L. Hedrich* 22
IF Stabilization by Regenerative Frequency Conversion, *D. M. Makow* 32
Correspondence
On Series of Rectangular Wave Functions and the Concept of Sign Correlation, *H. L. Armstrong* 36

Vol. I-8, No. 2, September, 1959

Abstracts 38
Broad-Band Radio Frequency Interferometer, *J. W. Carr* 39
Noise Measurement of Negative Resistance Amplifiers, *A. Brodzinsky and A. C. Macpherson* 44
Electrometer Measurements of Very Low Ion Densities in Gases, *R. L. Ramey and R. L. Overstreet* 46
Two Economical Circuits for High-Speed Checking of Contact Closures, *K. Enslein* 51
Optimization of the Aperture Corrective Systems, *J. Otterman* 55
PGI NEWS 62
Abstracts of Instrumentation Papers from the 1959 IRE CONVENTION RECORD 64

Vol. I-8, No. 3, December, 1959

Abstracts 66
Russian Test Equipment for Audio, Radio, and Microwave Measurements—Washington Chapter PGI, *B. O. Weinschel* 67
A Time Gate for Echo-Measuring Radar Installations, *J. Bacon and J. Q. Burgess* 79
A Transistor Temperature Analysis and Its Application to Differential Amplifiers, *W. Steiger* 82
Logarithmic Amplifier Design, *S. J. Solms* 91
Fundamental Limitations of External Noise, *H. H. Grimm* 97
Comparison of Deviations from Square Law for RF Crystal Diodes and Barretters, *G. U. Sorger and B. O. Weinsceh1* 103
Correspondence
Comments on Armstrong's Rectangular Wave Functions, *J. W. Cell and B. N. Tilley* 112
Contributors 112
Annual Index, 1959 *Follows page* 113

Medical Electronics

Vol. ME-6, No. 1, March, 1959

Preface 2
Welcoming Remarks, *C. Berkley* 3
Introduction, *P. F. Salisbury* 4
Organ Culture at the Rockefeller Institute (Summary of Talk), *G. W. Corner* 6
The Status of Extracorporeal Artificial Kidney, *W. J. Kolff* 7
The Prolonged Supplementation of Renal Function by Artificial Means, *P. F. Salisbury* 11
Blood Pumps, Conduits, and Valves, *C. A. Hufnagel* 13
Blood Gas Exchange Devices, *L. C. Clark, Jr.* 18
Magnetic Audition—Auditory Stimulation by Means of Alternating Magnetic Fields Acting on a Permanent Magnet Fixed to the Eardrum, *J. Rutschmann* 22
Information and Control in Organ System (Abstract), *W. A. Rosenblith* 23
Physiological Considerations, *J. F. Perkins, Jr.* 24
Artificial Respiration, *L. H. Montgomery and S. Stephenson* 29
CO_2 Control of Artificial Respiration, *M. J. Frumin* 30
Factors in the Control of the Circulation which may be Modified During Total Body Perfusion, *H. J. C. Swan* 32
An Efficient Blood Heat Exchanger for Use with Extracorporeal Circulation, *W. W. Smith* 34
Transistor for Cardiac Conduction System, *E. Watkins, Jr.* 36
Blood Vessels, *J. S. Edwards* 39
Artificial Mitral Valves, *J. H. Stuckey* 42
Plastic Cornea, *W. Stone, Jr.* 43
Tracheae, *R. E. Taber* 49
Gastrointestinal Tract, *W. E. Neville* 50
Silicone Rubber, *R. R. McGregor* 51
Plastics, *G. L. Hassler* 52
Diffusion of Oxygen and Carbon Dioxide Through Teflon Membranes, *E. C. Peirce, II* 54
Program 58
Roster of Conference Attendees 59

Vol. ME-6, No. 2, June, 1959

Simple Instrumentation in Medical Research, *J. Weinman and M. Robinson* 63
Investigation of Thermal Balance in Mammals by Means of Microwave Radiation, *B. S. Jacobson, S. B. Prausnitz, and C. Süsskind* 66
Time Lapse Ultraviolet Television Microscopy Instrumentation and Biological Applications, *G. Z. Williams* 68
Medical Applications of Fluoroscopic Image Intensification—I, *G. Henny* 75
Medical Applications of Fluoroscopic Image Intensification—II, *H. M. Stauffer* 78
Medical Applications of Fluoroscopic Image Intensification—III, *J. Kirkpatrick* 82

The Modification of Sensory Information by Neural Interaction in the Eye, and Its Relation to Vision, *H. K. Hartline* 84
Basic Mechanisms of Synaptic Transmission in the Central Nervous System, *K. Frank* 85
Biological Rhythms, *G. C. Stephens* 88
The Gibbon-Mayo Pump-Oxygenator, *R. E. Jones* 92
Radio Telemetering from Within the Human Body, *R. S. Mackay* 100

Vol. ME-6, No. 3, September, 1959

A Multichannel Analyzer for Hert Potentials, *C. V. Nelson, A. F. Wilkinson and L. W. Bowles* 107
Computers Applied to Ballistocardiography, *S. A. Talbot* 109
A New System for Electrocardiographic Recording, Analysis, and Diagnosis, *J. Martinek, G. C. K. Yeh, and R. Carnine* 112
A Study of the Advantages of Displaying the Heart's Electrical Activity as Linear Time-Scale Curves of Spatial Magnitude and Orientation, *J. A. Abildskov, E. D. Jacobson, S. Rush, and S. Zinberg* 116
The Computation of Muscle Activity from the Integrated Electromyogram, *B. R. Fink and M. L. Scheiner* 119
Automatic Reading and Recording of Digital Data in the Analysis of Primate Behavior, *D. McConnell, V. J. Polidora, M. P. Friedman, and D. R. Meyer* 121
The Human Being as a Link in an Automatic Control System—Part I, *T. J. Higgins and D. B. Holland* 125
Adaptive Servomechanisms, *C. W. Johnson* 134
Transmission of Ultrasound Through Living Human Thorax, *H. D. Crawford, J. J. Wild, P. I. Wolf, and J. S. Fink* 141
Problems in Electroencephalograph Analysis, *M. G. Saunders* 147
The Analysis of Electroencephalograms by the Use of a Cross-Spectrum Analyzer, *E. S. Krendel* 149
An Automatic Digital Recorder for Timing Sequential Events, *S. M. Block* 157
A Method of Measuring the Dynamic Characteristics of Muscle Rigidity, Strength, and Tremor in the Upper Extremity, *D. D. Webster* 159
Computational Aspects of Brain Function, *R. G. Bickford* 164
Digital Recording of Electrocardiographic Data for Analysis by a Digital Computer, *L. Taback, E. Marden, H. L. Mason, and H. V. Pipberger* 167
Possible Approaches to Multiple-Channel Tape Recording for Biomedical Purposes, *D. H. Smith, R. Moore, and J. Brault* 171
A Statistical Study of the Effects of Electric Fields on the Movements of Mammalian Sperm Cells, *J. W. Trank* 174
Autocorrelation and Crosscorrelation Analysis in Electroencephalography, *J. S. Barlow* 179

Contributions

An Automatic Pressure Regulator for Extracorporeal Circulation, *O. Z. Roy* 184
The Ultraviolet Flying-Spot Television Microscope, *P. O'B. Montgomery and W. A. Bonner* 186
PGME Application for Affiliates 190

Vol. ME-6, No. 4, December, 1959

Introduction, *L. B. Lusted* 193
Foreword, *F. L. Dunn and H. G. Beenken* 194
An Ultrasonic Flowmeter, *J. F. Herrick and J. A. Anderson* 195
Design Considerations for Ultrasonic Flowmeters, *W. R. Farrall* 198
Résumé of Discussion Group on Ultrasonic Flowmeters, *J. F. Herrick* 202
A Pulsed Ultrasonic Flowmeter, *D. L. Franklin, D. W. Baker, R. M. Ellis, and R. F. Rushmer* 204
Comparative Pulsatile Blood Flow Contours Demonstrating the Importance of RC Output Circuit Design in Electromagnetic Blood Flowmeters, *T. Cooper and A. W. Richardson* 207
Measurement of Cardiac Output in Unrestrained Dogs by an Implanted Electromagnetic Meter, *F. Olmsted* 210
Gated Sine-Wave Electromagnetic Flowmeter, *A. Westersten, G. Herrold, E. Abbott, and N. S. Assali* 213
Chopper-Operated Electromagnetic Flowmeter, *F. L. Abel* 216
The Square-Wave Electromagnetic Flowmeter: Theory of Operation and Design of Magnetic Probes for Clinical and Experimental Application, *M. P. Spencer and A. B. Denison, Jr.* 220
Electromagnetic Blood Flow Measurements in Extracorporeal Circuits, *A. R. Cordell and M. P. Spencer* 228
A Magnetic Flowmeter for Recording Cardiac Output, *H. W. Shirer, R. B. Shackelford, and K. E. Jochim* 232
An Integrating Drop-Flowmeter for Optical or Pen Recording, *C. N. Peiss and R. D. McCook* 234
Performance and Application of a Commercial Blood Flowmeter, *W. Thornton and B. Bejack* 237
The DC Electromagnetic Flowmeter and Its Application to Blood Flow Measurement in Unopened Vessels, *W. Feder and E. B. Bay* 240
Flowmeter for Extracorporeal Circulation, *G. Albertal, R. H. Clauss, A. M. Fosberg, and D. E. Harken* 246
Discussion of Orifice-Plate Flowmeter for Extracorporeal Circuit, *F. Robicsek* 249
Résumé of DC Electromagnetic Flowmeter Group Discussion, *W. Feder* 250
Certain Aspects of Hydrodynamics as Applied to the Living Cardiovascular System, *D. L. Fry* 252
The Measurement of Pulsatile Blood Flow by the Computed Pressure Gradient Technique, *D. L. Fry* 259
Methods of Flow Estimation by Pressure Sensing Techniques, *D. L. Fry* 264
Nonimpromptu Comment on Papers by Dr. Fry, *R. L. Evans* 266
Blood Flowmeter Utilizing Nuclear Magnetic Resonance, *R. L. Bowman and V. Kudravcev* 267
The Potter Electroturbinometer: An Instrument for Recording Total Systemic Blood Flow in the Dog, *S. J. Sarnoff and E. Berglund* 270
An Automatic Recording Bubble Flowmeter, *C. W. Nash and J. V. Milligan* 274
Use of Indicator Concentration Curves in Computation of Mean Rate of Flow and Volume of Blood Contained Within a Segment of the Vascular System, *H. D. Green, A. B. Denison, Jr., C. E. Rapela, and G. Lin* 277
Isothermal Blood Flow Velocity Probe, *S. Katsura, R. Weiss, D. Baker, and R. E. Rushmer* 283
A New Velocity Probe for Sensing Pulsatile Blood Flow, *A. M. Richards and F. W. Kuether* 286
Quantitative Measurement of Branched Flow by Externally Placed Radioisotope Detectors, *S. Thompson, G. Sevelius, D. Patrick, and P. Johnson* 287
Harmonic Analysis of Frequencies in Pulsatile Blood Flow, *D. J. Ferguson and H. S. Wells* 291
Critical Review of Bristle Flowmeter Techniques, *G. A. Brecher* 294
Index, 1959 *Follows page* 304

Microwave Theory and Techniques

Vol. MTT-7, No. 1, January, 1959

Message from The Chairman, *T. S. Saad* 2
Frontispiece, *W. L. Pritchard* 3
Education and Science in a Mature Society, *W. L. Pritchard* 4
Foreword, *A. L. Aden* 5
Microwave Radiation from Ferrimagnetically Coupled Electrons in Transient Magnetic Fields, *F. R. Morgenthaler* 6
Ferrite High-Power Effect in Waveguides, *E. Stern and R. S. Mangiaracina* 11
Temperature Effects in Microwave Ferrite Devices, *J. L. Melchor and P. H. Vartanian* 15
Characteristics of Ferrite Microwave Limiters, *G. S. Uebele* 18
Nonreciprocity in Dielectric Loaded TEM Mode Transmission Lines, *D. Fleri and G. Hanley* 23
Ferrite Phase Shifter for the UHF Region, *C. M. Johnson* 27
A Ferrite Serrodyne for Microwave Frequency Translation, *F. J. O'Hara and H. Scharfman* 32
Broad-Band Ferrite Rotators Using Quadruply-Ridged Circular Waveguide, *H. N. Chait and N. G. Sakiotis* 38
Present State of the Millimeter Wave Generation and Technique Arm—1958, *P. D. Coleman and R. C. Becker* 42
Millimeter-Wave Generation Experiment Utilizing Ferrites, *W. P. Ayres* 62
Some Characteristics of Dielectric Image Lines at Millimeter Wavelengths, *J. C. Wiltse* 65
The Interaction of Microwaves with Gas-Discharge Plasmas, *S. C. Brown* 69
High Power, Magnetic Field Controlled Microwave Gas Discharge Switches, *S. J. Tetenbaum and R. M. Hill* 73
Solid-State Microwave Amplifiers, *H. Heffner* 83
A UHF Solid-State Maser, *R. H. Kingston* 92
A Microwave Frequency Standard Employing Optically Pumped Sodium Vapor, *W. E. Bell, A. Bloom, and R. Williams* 95
Microwave Filter Design Using an Electronic Digital Computer, *L. Young* 99
Measurement of Two-Mode Discontinuities in a Multimode Waveguide by a Resonance Technique, *L. B. Felsen, W. K. Kahn, and L. Levey* 102
Mode Couplers and Multimode Measurement Techniques, *D. J. Lewis* 110
Measurement of Harmonic Power Generated by Microwave Transmitters, *V. G. Price* 116
Tunable Passive Multicouplers Employing Minimum-Loss Filters, *J. F. Cline and B. M. Schiffman* 121
A Wide-Band Strip-Line Balun, *E. M. T. Jones and J. K. Shimizu* 128
Periodic Structures in Trough Waveguide, *A. A. Oliner and W. Rotman* 134
A Study of a Serrated Ridge Waveguide, *H. S. Kirschbaum and R. Tsu* 142
Design Considerations for High-Power Microwave Filters, *S. B. Cohn* 149
Evacuated Waveguide Filter for Suppressing Spurious Transmission from High-Power *S*-Band Radar, *H. A. Wheeler and H. L. Bachman* 154
Hybrid Junction—Cutoff Waveguide Filters, *E. N. Torgow* 16

Practical Design of Strip-Transmission-Line Half-Wavelength Resonator Directional Filters, *R. D. Wanselow and L. P. Tuttle, Jr.* 168

Correspondence

A High Average Power Broad-Band Ferrite Load Isolator for *S* Band, *E. N. Skomal* 174
Reflection Coefficient of *E*-Plane Tapered Waveguides, *R. F. H. Yang and K. Matsumaru* 175
The Permeability Matrix for a Ferrite Medium Magnetized at an Arbitrary Direction and Its Eigenvalues, *G. Tyras* 176
Resistive-Film Calorimeters for Microwave Power Measurement, *J. A. Lane* 177
PGMTT News 178
Call for Papers for 1959 PGMTT National Symposium 180
Contributors 181

Vol. MTT-7, No. 2, April, 1959

Message from the Editor 188
Frontispiece, *S. B. Cohn* 189
Breaking Through the Mental Barrier, *S. B. Cohn* 190
Reflection of a Pyramidally Tapered Rectangular Waveguide, *K. Matsumaru* 192
Cascade Directional Filter, *O. Wing* 197
Propagation in a Dielectric-Loaded Parallel Plane Waveguide, *M. Cohn* 202
Electromagnetic Backscattering Measurements by a Time-Separation Method, *C. C. H. Tang* 209
On Network Representations of Certain Obstacles in Waveguide Regions, *H. M. Altschuler and L. O. Goldstone* 213
Reflectors for a Microwave Fabry-Perot Interferometer, *W. Culshaw* 221
Precise Control of Ferrite Phase Shifters, *D. D. King, C. M. Barrack, and C. M. Johnson* 229
Tables for Cascaded Homogeneous Quarter-Wave Transformers, *L. Young* 233
The Synthesis of Symmetrical Waveguide Circulators, *B. A. Auld* 238
Delay Distortion in Crystal Mixers, *T. Kawahashi and T. Uchida* 247
The Efficiency of Excitation of a Surface Wave on a Dielectric Cylinder, *J. W. Duncan* 257
Proposal for a Tunable Millimeter Wave Molecular Oscillator and Amplifier, *J. R. Singer* 268
High-Speed Microwave Switching of Semiconductors—II, *R. V. Garver* 272
A Logarithmic Transmission Line Chart, *A. C. Hudson* 277
The Far Fields Excited by a Point Source in a Passive Dissipationless Anisotropic Uniform Waveguide, *A. D. Bresler* 282
Analysis of a Negative Conductance Amplifier Operated with a Nonideal Circulator, *E. W. Sard* 288

Correspondence

Propagation Constants in Rectangular Waveguide Partially Filled with Dielectric, *W. L. Weeks* 294
A Short Rugged Ferrite Half-Wave Plate for a Single-Sideband Modulator, *H. I. Glass* 295
A Technique for Minimizing Hysteresis in a 35-DB Ferrite Variable Attenuator, *H. I. Glass* 295
Quarter-Wave Compensation of Resonant Discontinuities, *C. H. Muehe* 296
Comments on Ozaki's Comments, *H. J. Riblet* 297
Vector Formulations for the Field Equations in Anisotropic Waveguides, *A. D. Bresler* 298
An Extension of the Reflection Coefficient Chart to Include Active Networks, *L. J. Kaplan and D. J. R. Stock* 298
Characteristics of a Ferrite-Loaded Rectangular Waveguide Twist, *A. E. Barrington* 299

Analytical Asymmetry Parameters for Symmetrical Waveguide Junctions, *M. Cohen and W. K. Kahn* 430
Orthogonality Relationships for Waveguides and Cavities with Inhomogeneous Anisotropic Media, *A. T. Villeneuve* 441
Mismatch Errors in Cascade-Connected Variable Attenuator, *G. E. Schafer and A. Y. Rumfelt* 447
A Nonreciprocal TEM-Mode Structure for Wide-Band Gyrator and Isolator Applications, *E. M. T. Jones, G. L. Matthaei, and S. B. Cohn* 453
High Power Microwave Rejection Filter Using Higher Order Modes, *J. H. Vogelman* 461
A Method for Accurate Design of a Broad-Band Multibranch Waveguide Coupler, *K. G. Patterson* 466

Correspondence

The Analogy Between the Weissfloch Transformer Theorem and the Ideal Attenuator (Reflection Coefficient Transformer) and an Extension to Include the General Lossy Two-Port, *D. J. R. Stock and L. J. Kaplan* 473
Comments on "Some Notes on Strip Transmission Line and Waveguide Multiplexers," *B. M. Kurzrok* 475
The Representation of Impedance with Negative Real Parts in the Projective Chart, *D. J. R. Stock and L. J. Kaplan* 475
Design Calculations for UHF Ferrite Circulators, *H. Boyet, S. Weisbaum, and I. Gerst* 475
Discussion on Optimum Bead Spacing, *J. Reed and D. Dettinger* 477
Concerning Riblet's Theorem, *L. Young* 477
Broad-Band Stub Design, *L. Young* 478
Attenuation of the HE$_{11}$ Mode in the *H*-Guide, *M. Cohn and F. J. Tischer* 478
Experimental Determination of Wavelengths in Dielectric-Filled Periodic Structures, *E. Weissberg* 480
An Automatic Microwave Dielectrometer, *W. F. Gabriel* 481
Design Note on a Serrated Choke *W. F. Gabriel* 481
Contributors 482
Call for Papers for 1960 Symposium 485
Annual Index, 1959 *Follows page* 486

Military Electronics

Vol. MIL-3, No. 1, January, 1959

Frontispiece, *G. E. Valley, Jr.* 1
Guest Editorial, *G. E. Valley, Jr.* 2
Systems Engineering and Weapon System Management, *L. I. Davis* 4
Systems Engineering for Usefulness and Reliability, *W. C. Tinus and H. G. Och* 8
Systems Engineering, *R. H. Jewett and R. A. Montgomery* 12
Weapons Systems Management, *T. L. Phillips and I. A. Getting* 19
Contributors 23

Vol. MIL-3, No. 2, April, 1959

Frontispiece, *K. A. Ehricke* 25
Guest Editorial, *K. A. Ehricke* 26
Some Problems in Ionic Propulsion Systems, *E. Stuhlinger and R. Seitz* 27
Plasma Propulsion Device for Space Flight, *M. Camac, A. Kantrowitz, and H. E. Petschek* 34
Plasma Propulsion Possibilities, *W. Rayle* 42
A Brief Survey of Direct Energy Conversion Devices for Possible Space-Vehicle Application, *A. E. von Doenhoff and D. A. Premo* 46
Fusion for Space Propulsion, *S. H. Maslen* 52
Astronautics and Propulsion, *K. A. Ehricke* 58
Contributors 65

Vol. MIL-3, No. 3, July, 1959

Frontispiece, *E. C. Callahan* 67
Guest Editorial, *E. C. Callahan* 68
Design Considerations for a Celestial Navigation Trainer, *M. D. Bennett and N. B. Mickelson* 69
Synthetic Representation of Terrain Features on a Simulated Airborne Radar Display, *J. T. Slattery and M. Kamenetsky* 75
Development of the First Helicopter Operational Flight Trainer, *E. W. Cairns* 82
Simulation of Earth's Topography for Research and Engineering, *S. Domeshek* 87
An Integrated Space-Flight Simulator, *M. Ackerman* 92
The Human Disorientation Device—A Simulator of Angularly-Accelerated Motion, *J. H. Achilich* 99
A Land-Mass Radar Simulator Incorporating Ground and Contour Mapping and Terrain Avoidance Modes, *W. P. Jameson and R. M. Eisenberg* 105
Thirty-Two Aircraft Radar Track Simulator, *L. Packer, M. Raphael, and H. Saks* 114
Contributors 123

Vol. MIL-3, No. 4, October, 1959

Guest Editorial, *B. A. Schriever* 127
Scientific Objectives of the ABLE-3 Program, *Applied Physics Department, Space Technology Laboratories, Inc.* 129
ABLE-3 Payload Instrumentation, *J. E. Taber* 143
Three-Dimensional Interplanetary Trajectories, *A. B. Mickelwait, E. H. Tompkins, Jr., and R. A. Park* 149
Detection and Evaluation of Space Radiations, *deP. J. Corkhill and R. A. Hoffman* 160
High-Accuracy Electronic Tracking of Space Vehicles, *P. F. von Handel and F. Hoehndorf* 162
Some Reliability Aspects of Weapon and Other Space Systems Using Ballistic Missile Boosters, *H. Triwush* 173
Radar Beacons for IRBM/ICBM, *F. J. Clark* 175
Design Studies for a Rubidium Gas Cell Frequency Standard, *J. M. Andres, D. J. Farmer, and G. T. Inouye* 178
Some Considerations in the Design of the Guidance and Control System for Discoverer, *J. J. Schmitt, Jr.* 184
Contributors 185
Annual Index, 1959 *Follows page* 187

Nuclear Science

Vol. NS-6, No. 1, March, 1959

From the Editor, *R. F. Shea* 1
A Bias Function Generator for the Zero Gradient Synchrotron, *L. K. Wadhwa* 2
Servologarithmic Amplifier for Reactor Instrumentation, *W. J. Hartin* 11
Study of the Feasibility of a Ferrite Modulation System for an FM Cyclotron, *K. Enslein* 14
Nanosecond Pulse Transformers, *C. N. Winningstad* 26
A Chronotron for Relativistic Neutron Time-Off Flight Measurements, *R. H. Ragsdale and W. F. Stubbins* 31
Ion Phase Measurement Techniques on the Birmingham Cyclotron, *M. Konrad* 35

Vol. NS-6, No. 2, June, 1959

From the Editor, *R. F. Shea* 41
Transistorized Reactor Instrumentation and Protective Circuits, *R. R. Hoge and D. J. Niehaus* 42
Radiation Effects in Silicon Solar Cells, *F. A. Junga and G. M. Enslow* 49
Transistorized Log-Period Amplifier, *E. J. Wade and D. S. Davidson* 53
Transistorized Linear Pulse Amplifiers, *S. C. Baker* 57
Beam-Profile Indicator, *H. G. Jackson, D. A. Mack, and C. Wiegand* 64
The Trinistor Switch—A Solid-State Power Relay, *P. F. Pittman* 69
A Simplified Logarithmic Integrator Circuit, *H. E. DeBolt* 74
Announcement of the Sixth Annual National Meeting 78

Vol. NS-6, No. 3, September, 1959

A Post-Geneva Review of Controlled Thermonuclear Fusion, *E. W. Herold* 1
Report on the Geneva Conference: Developments in Controlled Fusion Electronics, *H. W. Van Ness* 11
Microwave Interferometer Measurements for the Determination of Plasma Density Profiles in Controlled Fusion Experiments, *C. B. Wharton and D. M. Slager* 20
Development of Switching Components for Controlled Fusion Research, *D. B. Cummings* 23
Experimental Measurements in Controlled Fusion Research, *M. A. Heald* 33
Papers on Controlled Thermonuclear Fusion 42

Vol. NS-6, No. 4, December, 1959

Effects of Reactor Exposure on Boron-Lined and BF$_3$ Proportional Counters, *W. M. Trenholme* 1
The Describing Function of Nuclear Reactors, *H. B. Smets* 8
Radiation-Tolerant Electronic Equipment, *J. R. Burnett* 12
Transistor-Driven Beam Switching Tube Decade Counter, *R. H. Graham* 16
A Stack Effluent Radioisotope Monitor, *R. A. Harvey* 20

Production Techniques

PGPT-4, June, 1959

Message from the Editor 1
Call for Papers 2
Chairman's Notebook 3
Design by Algorithm: A Mathematical Method of Designing Standard Assemblies for Minimum Manufacturing Cost, *D. H. Evans* 4
Design Improvement of an Airborne System Through Mathematical Prediction of Its Vibrations and Dynamics, *D. Ehrenpreis* 11
An Approach to Airborne Digital Computer Equipment Construction, *P. E. Boron and E. N. King* 18
Increased Reliability and Better Quality Control Through Mechanized Assembly and Test, *L. K. Lee and J. W. Buffington* 22
Ultrasonics Applied to Metal Fusion-Joining Processes, *E. E. Weismantel and J. G. Thomas* 28
An Investigation of Production Problems Relating to the Power-Carrying Capacity of a *K*-Band Microwave Component, *D. E. Davis and G. A. Moglia* 29
Administrative Committee 30
Standing and Working Committees 31
Calendar of Coming Events 32

PGPT-5, August, 1959

Index of Papers in This Issue 1
Message from The Editor 3
Frontispieces 4, 6, 8
Guest Editorials
  Organizing for Automation, *C. F. Horne* 5
  A Plea for Better Production Engineering, *E. G. Uhl* 7
  Production Characteristics of the Airborne Equipment Industry, *J. R. Moore* 9
Scanning the Issue, *A. R. Gray* 11
Modular Dimensioning of Electronic Component Parts for Mechanized Assembly, *R. A. Gerhold and W. V. Lane* 12
Future Component Parts for Mechanization, *E. W. Plesser* 17
Design Trends in Tomorrow's Capacitors, *A. A. Tiezzi* 20
Research and Development for Man-Machine Systems, *G. W. Hoover* 23
The "Tuf-Plate Hole" for Printed Wiring (Abstract), *G. B. Geddy* 27
Designing with Polystrip Flat-Wire Cables (Abstract), *A. L. Pugh, Jr. and S. J. Stein* 28
Impact of Transistors on Military Electronics Design (Abstract), *A. B. Jacobsen and J. C. Nicholas* 28
Micro-Modules: Component Parts and Materials Requirements, *S. F. Danko and V. J. Kublin* 29
A Punched-Card-Controlled Component-Part Insertion Machine, *H. K. Hazel* 39
Evolution of a System for the Production of Electronics Equipment—Mechanization of All Lot Sizes, *C. P. Cardani* 42
Microminiaturization Techniques (Abstract), *J. Finkelstein* 50
New Techniques in Potting, Encapsulating, and Small Parts Molding (Abstract) *J. L. Hull* 50
Automation of Single-Axis Floated-Gyro Drift Measurement, *J. G. Nelson* 51
PGPT Call for Papers 56

PGPT-6, September, 1959

Message from The Editor i
Scanning the Issue ii
Technique for Automatic Testing Electronic Components, *V. W. Walter and S. W. Nelson* 1
The Semiautomatic Circuit Component Tester, *F. C. Brammer* 12
Minimizing Production Costs Through Modular Automatic Test Equipment, *J. Tampico and H. B. Rose* 19
Some Aspects of the Thermal Design of Electronic Equipment Operating at 300–500°C Environmental Temperature, *J. P. Welsh* 25
Reliable Design and Development Techniques, *J. E. McGregor* 30
Management Views Automation, *I. Travis* 35

Radio Frequency Interference

Vol. RFI-1, No. 1, May, 1959

Control of Microwave Interference, *A. H. Ryan* 1
Analysis of Through-Channel and Cross-Channel Insertion Loss in Ferrite-Wall Multiple-Circuit Feedthrough Capacitors, *I. Melngailis, E. M. Williams, and J. H. Foster* 11
Design of Quasi-Peak Detectors with Specified Time Constants, *V. Peless* 18
Biographies of the Authors 24

Reliability and Quality Control

PGRQC-16, June, 1959

Address to the Fifth National Symposium on Reliability and Quality Control, *W. T. Thurman* 1
Making a Multiplant Supplier Rating System Produce, *P. J. Goldin* 7
The Heart of a Reliability Program, *A. Mood* 16
The Relation Between Sample Size and Confidence in Test-to-Failure Reliability Programs, *H. C. Jones* 24
A Reliability Analysis of Recoverable Missiles, *G. G. den Broeder, Jr. and W. E. Kane* 34
The Employment of Failure Rate Data in Logistic Planning, *J. B. Heyne and L. Brotman* 41
Module Prediction, *G. Hauser* 53
An Approximate Method of Forming a Confidence Interval on Predicted System Reliability, *R. E. Warr, J. A. Navarro, R. Schwartz, and R. D. Turner* 64
Increased System Worth Through Reliability Design Review, *R Cazanjian and D. Ehrenpreis* 70
An Evaluation of Torque-Rated Ball Bearings, To Establish Specification Limits, *L. G. Rado and J. P. Tuggle* 77
Announcement Back Cover

Space Electronics and Telemetry

Formerly Telemetry and Remote Control

Vol. SET-5, No. 1, March, 1959

Follows TRC-4

Data Collection Problems in Second Generation Ballistic Missiles, *L. C. Sackett* 1
An Automatic Data Handling System at High Speed and High Capacity, *R. L. Sink, C. E. Pettingall, and B. N. Posthill* 8
Instrumentation and Range Safety System for Vandenberg Air Force Base, *R. E. Hadady* 14
Some Observation on the Challenging Aspects of the Telemetry Field, *L. E. Root* 28
Basic Theory of Locked Oscillators in Tracking FM Signals, *G. W. Preston* 30
Frequency Domain Applications to Data Processing, *M. A. Martin* 33
A Digital System for Position Determination, *D. C. Ross* 42
Some Properties of the Gravitation Field and Their Possible Application to Space Navigation, *J. C. Crowley, S. S. Kolodkin, and A. M. Schneider* 47
Proceedings of The 1958 National Symposium on Telemetering 54

Vol. SET-5, No. 2, June, 1959

Electromechanical Energy Conversions in a Cylindrical Pinch Process, *J. L. Neuringer* 55
Problems of Ground Simulation of Long-Range Space Flight Environmental Conditions, *T. C. Helvey* 57
Consideration of RF Parameters for PCM Telemetry Systems, *D. D. McRae* 61
A Digital Computer System for Terminal-Area Air Traffic Control, *E. L. Braun and A. S. Gianoplus* 66
Glossary of Astronautics Terminology, *D. C. Madrid* 73
A Super-Fast, Carrier Quieted Telemetry System for Missile Impact Instrumentation, *J. L. Wright and J. C. Ruscus* 76
Short-Distance Radio Telemetering of Physiological Information, *H. G. Beenken and F. L. Dunn* 82
Operational Characteristics of the TLM-18 Automatic Tracking Telemetry Antenna, *F. S. Coxe* 87
Contributors 91

Vol. SET-5, No. 3, September, 1959

Communication Techniques for Space Exploration, *E. Rechtin* 95
Telemetered Parameters of Primates and Humans from Space Capsules, *T. C. Helvey* 99
A Circularly Polarized Feed for an Automatic Tracking Telemetry Antenna, *R. C. Baker* 103
The Dynamic Analysis of the Averaging Type FM Discriminator, *I. Cederbaum and S. Rozenstein* 111
A High-Speed, Airborne Digital Data Acquisition System, *S. Cogan and W. K. Hodder* 117
A System for Editing and Computer Entry of Flight Test Data, *S. F. Higgins* 123
The Use of a Fractional Bi-Stable Multivibrator Counter in the Design of an Automatic Discriminator Calibrator, *M. W. Williard and G. F. Anderson* 131
Analysis of Multiplex Error in FM/FM and PAM/FM/FM Telemetry, *J. Schenck and W. F. Kennedy* 138
Comments Relative to the Application of PCM to Aircraft Flight Testing, *R. S. Djorup* 148
Contributors 153

Vol. SET-5, No. 4, December, 1959

A Rocket for Manned Lunar Exploration, *M. W. Rosen and F. C. Schwenk* 155
Contemporary Plasma Physics, *L. Gold* 162
A New Approach to the Linear Design and Analysis of Phase-Locked Loops, *C. S. Weaver* 166
Space-To-Ground Transmissions Beyond the Line-of-Sight Distance, *J. Galejs* 179
The Application of Radio Interferometry to Extraterrestrial Metrology, *M. J. E. Golay* 186
Standards for Pulse Code Modulation (PCM) Telemetry, *Telemetry Working Group* 194
The Tracking of Pioneer IV: The Elements of a Deep Space Tracking System (Abstract), *H. L. Richter, Jr. and R. Stevens* 196
An Interplanetary Communication System, *G. E. Mueller and J. E. Taber* 196
Deltamodulation for Cheap and Simple Telemetering, *F. K. Bowers* 205
Contributors 209
Annual Index, 1959 *Follows page* 210

Ultrasonics Engineering

PGUE-7, February, 1959

PGUE Award 1
Biographical Notes on the Award Winners 2
An Ultrasonic Cleaner for Hypodermic Needles and Similar Small Bore Apparatus, *F. Nesh and J. R. Andreotti* 3
Ultrasonic Atomization of Liquids, *J. N. Antonevich* 6
Theory of Magnetostrictive Delay Lines for Pulse and Continuous Wave Transmission, *R. C. Williams* 16
Biographical Notes on the Authors 39

Vehicular Communications

PGVC-12, April, 1959

Investigation of Antennas for Two-Way Mobile Communications in the VHF and UHF Regions, *E. F. Harris* 2
Antenna-to-Mast Coupling in Communication, *M. W. Scheldorf* . . 5
Identifying 450 MC Interference Using a Tunable Receiver and a Panadapter, *R. J. Klein* 13
Transmission Tests on a Trial System of Telephone Service for Aircraft, *R. V. Crawford* 20
Shadows of the Future in Vehicular Communication, *D. C. Pinkerton* 27
A New Era in Communications Through Transistors, *W. J. Weisz* . 35
Bias Considerations in Transistor Applications to Communications Circuitry, *A. G. Manke* 47
Transistorized Power Supplies for Higher Input Voltages, *L. S. Pearlman* 54
The Use of Miniature Tubes in Class C Circuits, *A. Dzik* 58
Application of Vehicular Communications to Railroads, *L. R. Thomas* 62
Selective Signaling in the Bell System—Relay to Transistor, *W. G. Chaney* 67
A Transistorized Selector Device for Bell System Mobile Telephone Service, *J. R. Scantlin* 71
A Digital Selective Signaling System for Mobile Radio, *J. H. Green and J. Gordon* 74
New Ruggedized Hand-Held Microphone for Mobile Radio Equipment, *A. Brouns, G. Salisbury and R. Troxel* 86

PGVC-13, September, 1959

Meeting the Demands for Vehicular Communications, *C. B. Plummer* 1
Interference—a Look at the Ounce of Prevention, *N. H. Shepherd and A. C. Giesselman* 4
Operation of Close-Spaced Antennas in Radio Relay Systems, *W. F. Biggerstaff* 11
A Report on Interference Caused by Intermodulations Products Generated In or Near Land Mobile Transmitters, *N. H. Shepherd* 16
A VHF Pocket Receiver, *J. F. Mitchell* 20
Motor Carrier Mobile Radio Systems, *C. Johnston* 24
An Analysis of Radio Flutter in Future Communications, *N. W. Feldman* 27
FM Interference and Noise-Suppression Properties of the Oscillating Limiter, *E. J. Baghdady* 37
A New Approach to Compactness in Mobile Radio-Telephone Design, *W. Ornstein* 64
A New Manual Mobile Telephone System, *A. F. Culbertson* 73
Performance of "Low-Plate-Potential" Tube Types at Mobile-Communications Frequencies (Abstract), *R. J. Nelson and C. Gonzales* 83

COMBINED INDEX TO AUTHORS

Code numbers refer to papers as given in the contents list for each Professional Group. The letters in the code number designate the particular Professional Group, as follows:

ANE:	Aeronautical and Navigational Electronics
AP:	Antennas and Propagation
AU:	Audio
AC:	Automatic Control
BTR:	Broadcast and Television Receivers
BC:	Broadcasting (Formerly Broadcast Transmission Systems)
CT:	Circuit Theory
CS:	Communications Systems
CP:	Component Parts
E:	Education
ED:	Electron Devices
EC:	Electronic Computers
EM:	Engineering Management
EWS:	Engineering Writing and Speech
IE:	Industrial Electronics
IT:	Information Theory
I:	Instrumentation
ME:	Medical Electronics
MTT:	Microwave Theory and Techniques
MIL:	Military Electronics
NS:	Nuclear Science
PT:	Production Techniques
RFI:	Radio Frequency Interference
RQC:	Reliability and Quality Control
SET:	Space Electronics and Telemetry (Formerly Telemetry and Remote Control)
UE:	Ultrasonics Engineering
VC:	Vehicular Communications

COMBINED INDEX TO SUBJECTS

A

- ABLE-3 Payload Instrumentation: MIL Oct 143
- ABLE-3 Program, Scientific Objectives of: MIL Oct 129
- Adaptive Systems:
  - Bibliography: AC May 65
  - Control Processes: AC Nov 1
  - Control Processes, Dynamic Programming Approach to: AC Nov 10
  - Control Systems: AC Nov 30
  - Control Systems, Parameter Tracking Servo for: AC Nov 100
  - Flight Control: AC Dec 113
  - Function Optimization by the *Z*-Transform Method: AC Dec 172
  - Functional Equations in: CT May 271; IT May 271
  - Identification and Command Problems in: AC Nov 121
  - Servomechanisms: ME Sep 134
- Administering Information Input and Output in Research Laboratories: EM Jun 55
- Admittances, RC Constant-Argument Driving-Point: CT Sep 310
- Admittance, Terminal, of Dielectric Rod: AP Jul 207
- Air Duel Environment, Simulation of: EC Mar 55
- Air, High-Temperature, Electromagnetic Properties of: AP Dec S337
- Air Traffic Control, Automatic Communication System for: CS Jun 71
- Air Traffic Control, Digital Computer for Terminal-Area: SET Jun 66
- Airborne:
  - Digital Computer Equipment Construction: PT Jun 18
  - Digital Data Acquisition System: SET Sep 117
  - Dual Antenna System for Aerial Navigation: ANE Dec 211
  - Radar Display, Simulated, Synthetic Representation of Terrain Features on: MIL Jul 75
  - System Mathematical Prediction of Vibration and Dynamics: PT Jun 11
- Aircraft:
  - Crash Position Indicator for: ANE Sep 222
  - Data Link, Simplified: CS Jun 133
  - Flight Testing, Application of Pulse Code Modulation to: SET Sep 148
  - Radar Track Simulator, Thirty-Two: MIL Jul 114
  - Secondary Power Generator with Direct Compensation Frequency Control: CP Dec 259
  - Telephone Service for: VC Apr 20
- Algebra, Matrix, Applications to Network Theory: CT May 127; IT May 127
- Algebraic Equations, Linear, Flow-Graph Solutions of: CT Jun 170
- Alloyed Junctions in Silicon, Making Crack-Free: ED Jul 358
- Alpha, High-Frequency, Cutoff Jig: ED Apr 242
- Ambiguity and Distance Functions, Invariant Relations for: IT Dec 164
- American Automatic Control Council: AC May 5
- Amplifiers:
  - Audio, with Reduced Plate Dissipation: AU Mar–Apr 29
  - Backward-Wave, for Microwave Autodyne Reception: MTT Jul 356
  - Degenerative, Having a Base-Emitter Shut Impedance: AU Nov–Dec 165
  - Differential, Transistor Temperature Analysis for: I Dec 82
  - Direct-Coupled, Utilizing a Clipper-RC Feedback Loop: BTR Dec 8
  - Klystron, Low-Noise: ED Oct 428
  - Logarithmic Design: I Dec 91
  - Molecular, Millimeter Wave: MTT Apr 268
  - Negative Conductance, with a Nonideal Circulator: MTT Apr 288
  - Negative Resistance, Noise Measurement of: I Sep 44
  - Operational, for Four-Quadrant Multiplier: EC Jun 222
  - Parametric, Circuit Aspects of: BTR Dec 75
  - Parametric, Lossless Periodically Distributed, Mode Theory of: MTT Jul 360
  - Parametric Variable-Capacitance: ED Apr 216
  - RC, Design of Transistor: AU Jan–Feb 22
  - Response, Effect of Power Source Regulation on: AC Dec 59
  - RF Transistor, Cross Modulation and Nonlinear Distortion in: ED Oct 457
  - Semiconductor Diode, and Pulse Modulators: ED Jul 341
  - Servologarithmic, for Reactor Instrumentation: NS Mar 11
  - Single Side-Band Power: CS May 53
  - Solid-State Microwave: MTT Jan 83
  - for TV Receivers, Transistor IF: BTR May 25
  - Transistor Audio, Two-Watt: AU Sep–Oct 125
  - Transistorized Linear Pulse: NS Jun 57
  - Transistorized Log-Period: NS Jun 53
  - Transistor, Unilateralized: AU Mar–Apr 36
- Amplitron, Theory of: ED Oct 419
- Analog Computation, Time Multiplexing Applied to: EC Mar 42
- Analog to Digital Converter: EC Mar 31
- Analog Method for Constructing a Curve: EC Mar 68
- Analog Simulation, Operational, of the Vibration of a Structure: EC Sep 381
- Analyzer, Multichannel, for Heart Potentials: ME Sep 107
- Angle Modulation by a Combination of a Periodic Function and Noise: IT Dec 186
- Angle Modulation by a Mixture of a Periodic Function and Noise: IT Sep 140
- Angular Diversity Reception at 2290 MC: CS Sep 195
- Anistropic Layers, Propagation of Electromagnetic Waves through: AP Dec S296
- Antennas:
  - Airborne Dual System for Aerial Navigation: ANE Dec 211
  - Arrays, Glide-Slope: ANE Jun 100
  - Asymmetrical Trough Waveguide: AP Apr 153
  - Automatic Tracking Telemetry: SET Jun 87
  - Broadband Multislot: AP Dec S412
  - Cheese, Reduction of Scattering from Feed of: AP Jul 226
  - on Circular Cylinders: AP Dec S361
  - Close-Spaced, in Radio Relay Systems: VC Sep 11
  - Corner-Reflector, Gains of: AP Jul 281
  - Coupled System, Approximation of Impedance Parameters in: AP Oct 373
  - Coupling to Mast, in Communication: VC Apr 5
  - Cylindrical, Radiation Between Parallel Plates: AP Apr 162
  - Dipole, Coupled to a Two-Wire Transmission Line: AP Oct 386
  - Elliptical Helical, Field of: AP Jan 46
  - Equiangular Spiral: AP Apr 181, Dec S117
  - Feed for Tracking Telemetry: SET Sep 103
  - Finite Conical: AP Dec S406
  - Flush-Mounted Leaky-Wave: AP Oct 320
  - Helical, Bandwidth of: AP Dec S379
  - Leaky Wave, Rectangular Waveguides: AP Oct 307
  - Loaded Biconical, Resonance and Supergain Effects in: AP Dec S414
  - Null Filling by Off-Path Scattering: AP Jul 277
  - Omnidirectional Vertically Polarized Paraboloid: AP Apr 201
  - Pattern Calculations, Numerical Integration Methods for: AP Dec S387
  - Rectangular Loop, as a Dipole: AP Jan 53
  - Rhombic Arrays, Design of: AP Jan 39
  - Rhombic, Gain and Current Attenuation of: AP Apr 188
  - Scanning Arrays of Discrete Elements: AP Oct 435
  - Scanning, Spherical Reflectors as: AP Jul 223
  - Scanning Surface Wave: AP Jul 276
  - Scattering Problems, Numerical Solution of: AP Dec S402
  - Suppressed Sidelobe, of 32 Elements: AP Jan 101
  - Switching System, 50 KW: CS Dec 295
  - Thin Wire Loop Embedded in a Spherical Medium: AP Oct 345
  - Traveling-Wave Cylindrical: AP Jan 74
  - Two-Way Mobile Communications: VC Apr 2
  - Unidirectional Equiangular Spiral: AP Oct 329
  - URSI Report and Bibliography: AP Jan 87
  - Yagi, Obtaining Maximum Gain From: AP Oct 379
- Anticipatory Display Design Through the Use of an Analog Computer: ANE Dec 228
- Aperture:
  - Circular, Diffraction of Scalar Waves by: AP Dec 512
  - Corrective Systems: I Mar 8
  - Corrective Systems, Optimization of the: I Sep 55
  - Coupling to Medium: AP Apr 142
  - Distributions, Random Errors in: AP Oct 369
- Approximation, Impulse Train, for Time-Varying Linear System Synthesis in the Time Domain: CT Dec 393
- Approximation to a Prescribed Time Response, Improving: CT Dec 355
- Arctic Region, Propagation of HF and VHF in: CS Jun 121
- Argon Noise Source Tubes at *S*-Band: MTT Jul 395
- Arithmetic Operations for Digital Computers Using a Modified Reflected Binary Code: EC Dec 449
- Arizona Engineering Curriculum, Physics Courses in: E Sep 117
- Arrays:
  - Circular, to Obtain Omnidirectional Patterns: AP Oct 436
  - Helical Elements, Complex Mutual Impedance Between: AP Jul 279
  - Linear, Currents, Impedances, and Fields of: AP Dec S440
  - Long End-Fire Dipole, Calculated Phase Velocity of: AP Dec S424
  - Scanning Antenna, of Discrete Elements: AP Oct 435
- Artificial Kidney, Extracorporeal: ME Mar 7
- Artificial Mitral Valves: ME Mar 42
- Artificial Respiration: ME Mar 29
- Artificial Respiration, CO_2 Control of: ME Mar 30
- Assembly, Mechanized, Modular Dimensioning of Component Parts for: PT Aug 12
- Astronautics and Propulsion: MIL Apr 58
- Astronautics Terminology, Glossary of: SET June 73
- Atmospheric Duct Influence on Microwave Fading: AP Jul 252
- Atmospheric Refraction, Comparison of Computed with Observed: AP Jul 258
- Attenuation in Wedge and Septate Waveguides: AP Dec S279
- Attenuator:
  - Calibration, Signal Generator, Voltmeter for: I Mar 22
  - Cascade-Connected Variable, Mismatch Errors in: MIT Oct 447
  - Ferrite Variable, Minimizing Hysteresis in: MTT Apr 295
  - Ideal, Analogy Between the Weissfloch Transformer Theorem and: MTT Oct 473
- Attitude Control, Reaction Wheel, for Space Vehicles: AC Dec 139
- Attitude Control of Space Vehicles: AC Dec 34
- Audio:
  - Amplifier with Reduced Plate Dissipation: AU Mar–Apr 29
  - Applications of a Sheet-Beam Deflection Tube: BTR Dec 3
  - Circuits of Transistorized Broadcast Receivers: BTR Dec 46
  - Output System, Sliding Class-A: AU Jan–Feb 14
  - Pentode, Frame-Grid, for Stereo Output: AU Jul–Aug 101
  - Transistor Amplifier, Two-Watt: AU Sep–Oct 125

Auditory Stimulation by Magnet Fixed to Eardrum: ME Mar 22
Auroral Echoes, 400-MC Radar Investigations of: AP Apr 127
Authors, Turning Engineers into: EWS Dec 75
Autocorrelation and Crosscorrelation Analysis in Electroencephalography: ME Sep 179
Autodyne Reception, Microwave, Backward-Wave Amplifier for: MTT Jul 356
Automated Teaching, Preliminary Studies in: E Jun 104
Automatic Control System, Human as a Link in: ME Sep 125
Automatic Control Systems, *D*-Decomposition Analysis of: AC Dec 150
Automatic Control of Vector Quantitities: AC May 21
Automatic Control of Video Tape Equipment at NBC: BC Feb 5
Automatic Gain Control Circuit, A New: BTR Jan 5
Automatic Landing System: ANE Jun 128
Automatic Machine Tool Operation, Positioning Servo for: IE Jan 31
Automatic Mail Cancelling and Facing, Electronics in: IE Apr 14
Automatic Manufacturing in General Industry, Numerical Control for: IE Jul 33
Automatic Packaging of Gelatin Capsules: IE Jan 34
Automatic Rearview Mirror: IE Jul 43
Automatic Sweep Circuits and Signal-Seeking Receivers, Voltage Variable Semiconductor Capacitor in: BTR Dec 16
Automatic Test Equipment, Minimizing Production Costs Through Modular: IE Apr 29
Automatic Test Equipment, Modular, Minimizing Production Costs Through: PT Sep 19
Automatic Testing of Components: PT Sep 1
Automatically Controlled Vertical Turret Lathe, An: IE Apr 19
Automation, Management Views: IE Jan 59; PT Sep 35
Automation of Single-Axis Floated-Gyro Drift Measurement: PT Aug 51
Automation Trends in the Banking Industry: IE Jul 3
Automobile Receiver Front End Design, Transistor: BTR Dec 31
Automobile Receiver, Transistor, Employing Drift Transistors: BTR Dec 38

B

Back-Scattering Measurements with a Space-Separation Method: AP Jan 15
Back-Scattering Measurements by a Time-Separation Method: MTT Apr 209
Back-Scattering, Near-Field, Geometrical Optics, Approximation of: AP Oct 434
Backward-Wave Amplifier for Microwave Autodyne Reception: MTT Jul 356
Backward-Wave-Oscillator Starting Current, Effect of Beam Velocity Variation on: ED Oct 437
Ball Bearings To Establish Specification Limits, Evaluation of: RQC Jun 77
Ballistocardiography, Computers Applied to: ME Sep 109
Balun, Wide-Band Strip-Line: MTT Jan 128
Bandwidth of Helical Antennas: AP Dec S379
Banking Industry, Automatation Trends in the: IE Jul 3
Barretters, Crystal Diodes and, Deviations from Square Law for: I Dec 103
Bead Spacing, Optimum: MTT Oct 477
Beam, Collimated Circularly Polarized, Method to Achieve: AP Jul 281
Beam-Profile Indicator: NS Jun 64
Beam, Transistor-Driven, Switching Tube Decade Counter: NS Dec 16
Behavior, Primate, Automatic Recording of Digital Data in the Analysis of: NE Sep 121
Berkeley, Energy Conversion and Control at: E Sep 138
Bernoulli Sequence, Recurrent Events in a: IT Dec 179
Beyond the Horizon, Diffraction Theory of Tropospheric Propagation: AP Jul 261, 268
Beyond-the-Horizon Propagation, Sweep-Frequency Studies in: AP Oct 428
Beyond the Line-of-Sight, Space-To-Ground Transmissions: SET Dec 179
Bias Considerations in Transistor Applications: VC Apr 47
Bias Function Generator for the Zero Gradient Synchrotron: NS Mar 2

Bibliography:
    Adaptive or Self-Optimizing Control Systems: AC May 65
    and Antennas and Waveguides, URSI Report on: AP Jan 87
    of Digital Magnetic Circuits and Materials: EC Jun 148
    on Electroluminescence: ED Apr 203
    Logical Machine Design: EC Sep 367
    Transportation Lag: AC May 56
Binary Channels, Error-Correcting Codes for Asymmetric: IT Jun 62
Binary Numbers Modulo Three, Residues of: EC Jun 229
Binary Time Series in Periodic Functions: EC Jun 228
Biological Control System, Nonlinear Control, Techniques Employed by: AC Dec 45
Biological Rhythms: ME Jun 88
Biomedical Multiple-Channel Tape Recording: ME Sep 171
Biquadratic Minimum Function, Minimal Realizations of: CT Dec 345
Blood Flowmeters:
    Automatic Recording Bubble: ME Dec 274
    Bristle, Techniques: ME Dec 294
    Chopper-Operated Electromagnetic: ME Dec 216
    Commercial, Performance and Application of: ME Dec 237
    DC Electromagnetic, and Its Application: ME Dec 240: Discussion of: ME Dec 250
    Design Considerations for Ultrasonic: ME Dec 198
    Electromagnetic Blood Flow Measurements in Extracorporeal Circuits: ME Dec 228
    Electromagnetic, Output Circuit Design in: ME Dec 207
    for Extracorporeal Circulation: ME Dec 246: Discussion of: ME Dec 249
    Flow Estimation by Pressure Sensing Techniques: ME Dec 264: Discussion of: ME Dec 266
    Gated Sine Wave Electromagnetic: ME Dec 213
    Harmonic Analysis of Frequencies in Pulsatile Blood Flow: ME Dec 291
    Hydrodynamics As Applied to the Living Cardiovascular System: ME Dec 252; Discussion of: ME Dec 266
    Implanted Electromagnetic, Measurement of Cardiac Output in Dogs by: ME Dec 210
    Integrating Drop, for Optical or Pen Recording: ME Dec 234
    Isothermal Blood Flow Velocity Probe: ME Dec 283
    Magnetic, for Recording Cardiac Output: ME Dec 232
    Measurement of Branched Flow by External Radioisotope Detectors: ME Dec 287
    Measurement of Pulsatile Blood Flow by the Computed Pressure Gradient Technique: ME Dec 259: Discussion of: ME Dec 266
    Potter Electroturbinometer: ME Dec 270
    Pulsed Ultrasonic: ME Dec 204
    Square-Wave Electromagnetic Operation and Design: ME Dec 220
    Ultrasonic: ME Dec 195
    Ultrasonic; Discussion of: ME Dec 202
    Use of Indicator Concentration Curves in Computation of: ME Dec 277
    Utilizing Nuclear Magnetic Resonance: Me Dec 267
    Velocity Probe for Sensing Pulsatile Blood Flow: ME Dec 286
Blood Gas Exchange Devices: ME Mar 18
Blood Heat Exchanger for Use with Extracorporeal Circulation: ME Mar 34
Blood Pumps, Conduits, and Valves: ME Mar 13
Blood Vessels: ME Mar 39
BOMARC Guidance, Non-Real-Time Simulation of SAGE Tracking and: EC Mar 26
Boolean Functions:
    Absolute Minimal Expressions of: EC Mar 3
    Branch-Networks, Irredundant and Redundant: CT May 158; IT May 158
    Classification of: CT May 176; IT May 176
    Equations, Solution to: EC Jun 230
    Matrix Equations in Digital Circuit Design: EC Jun 131

Boundary Value Problem and Finite Range Wiener-Hopf Integral Equation in a Waveguide: AP Dec S244
Brain Function, Computational Aspects of: ME Sep 164
Branch-Networks, Irredundant and Redundant Boolean: CT May 158
Breaking Through the Mental Barrier: MTT Apr 190
Brillouin Flow, RF Current Distribution in: ED Jul 352
Bristle Flowmeter Techniques: ME Dec 294
Broadcast Switching System, Preset: BC Feb 1
Broadcast System, Optimized Compatible AM Stereophonic: BC Nov 2
Brune's Cycle, Alternative Derivation of: CT Dec 389
Burroughs Electrostatic Techniques, High-Speed Terminal Printers Using: CS Jun 125

C

Cables, Polystrip Flat-Wire, Designing with: PT Aug 28
Calorimeters, Resistive-Film, for Microwave Power Measurement: MTT Jan 177
Camera Tubes, Electrostatic Optics for: ED Jul 297
Capacitance of Two Infinite Cones: AP Jan 102
Capacitors:
    1959: CP Sep 150
    Design of High Frequency *p-n* Junction Variable: ED Jul 347
    Diffused Silicon Nonlinear: ED Oct 384
    Insertion Loss in Feedthrough: RFI May 11
    Plastic Dielectric: CP Jun 114
    Tomorrow's, Design Trends in: PT Aug 20
    Voltage Variable Semiconductor, in Automatic Sweep Circuits and Signal-Seeking Receivers: BTR Dec 16
Carbon Dioxide Diffusion Through Teflon Membranes: ME Mar 54
Cardiac Conduction System, Transistor for: ME Mar 36
Cardiac Output, Measurement in Dogs by Implanted Electromagnetic Flowmeter: ME Dec 210
Cardiac Output, Recording, Magnetic Flowmeter for: ME Dec 232
Cardiovascular System, Living, Hydrodynamics As Applied to: ME Dec 252; Discussion of: ME Dec 266
Cascaded Circuits, Determinant Relating To: CT Mar 134
Cathode, Dispenser, Magnetrons: ED Jan 115
Cathode Interface Impedance, Measurement of: ED Jul 315
Cathode, Magnetron, Arm Radiation and Luminescence: ED Apr 242, Oct 468
Caustic, Fields in the Neighborhood of: AP Dec S255
Cavities, Open-Ended Resonant, Design of: MTT Jul 389
Cavities and Waveguides with Inhomogeneous Anisotropic Media: MTT Oct 441
Cavity, Ferrite-Filled Cylindrical: AP Dec S273
Cavity Resonators, *X*-Band, End Plate Modification of: MTT Jul 388
Celestial Navigation Trainer: MIL Jul 69
Ceramics, High Dielectric Constant: CP Dec 238
Channel Selection for Interference-Free Operation: CS May 7
Channels, Cross Correlation Between Noisy: IT Jun 77
Characteristic Impedance of Split Coaxial Line: MTT Jul 393
Character Recognition Systems, Optimum: EC Jun 230
Checking of Contact Closures, Circuits for High-Speed: I Sep 51
Chemical Processing, Data-Gathering in Continuous: IE Jul 8
Chronotron for Relativistic Neutron Time-Of-Flight Measurements: NS Mar 31
Circuit Analysis, Notation of: CT Dec 391
Circuit Matrix, Realizability of: CT Jun 219
Circulation, Extracorporeal, Automatic Pressure Regulator for: ME Sep 184
Circulation, Factors Controlling: ME Mar 32
Circulators, UHF Ferrite, Design Calculations for: MTT Oct 475
Circulators, Waveguide, Synthesis of: MTT Apr 238
Coaxial Line, Split, Characteristic Impedance of: MIT Jul 393

- Codes:
  - Binary Systematic, Correcting Errors Occurring at Random and in Bursts: CT May 79; IT May 79
  - Code-Word Sets, Full Decodable: IT Mar 12
  - Error Correcting, for Asymmetric Binary Channels: IT Jun 62
  - Error-Correcting, Characteristics of: IT Jun 91
  - Error-Correcting, Orthogonal Matrices and Matrix Switches: EC Sep 400
  - Error-Correcting *p*-nary, Application of Modular Sequential Circuits to: IT Sep 114
  - of Finite Length, Upper Bounds for Error Detecting and Correcting: IT Dec 168
  - Modified Reflected Binary, Arithmetic Operations Using: EC Dec 449
  - Multi-Error Correcting, for a Binary Asymmetric Channel: IT May 71; CT May 71
  - Optimum, Group Code Equivalence and: IT May 60; CT May 60
  - A Ring Model for Multiplication for Complement: EC Mar 25
  - Systematic, for Non-Independent Errors: IT Dec 150
- Coding:
  - Externał, for Speech Transmission: IT Sep 129
  - Lossless Symbol, with Nonprimes: IT Mar 33
  - Networks, Linear Multivalued Sequential: CT Mar 69
  - of Pictures, Run-Length, Probabilistic Model for: IT Dec 157
- Coherent Optical Data Processing: AC Nov 137
- Collector Employing an Asymmetrical Electrode: ED Jul 294
- College Recruiting: E Mar 10
- Collimated Circularly Polarized Beam, Method to Achieve: AP Jul 281
- Color, Television Receiver, Decoder Design: BTR Jan 27
- Color TV Receivers, Simplification of Controls on: BTR May 54
- Communications:
  - Air Traffic Control, Automatic System: CS Jun 71
  - Digital Phase-Modulation Systems: CS May 3
  - Frequencies for High-Frequency, Effect of Multipath Distortion on the Choice of: AP Oct 397
  - Network, Analog Computer for Finding an Optimum Route Through a: CS May 37
  - Optical, During Hypersonic Re-Entry: CS Jun 68
  - Reliability, Radio Link: CS May 47
  - Space, Doppler Phenomena in: CS May 25
  - System, Interplanetary: SET Dec 196
  - Techniques for Space Exploration: SET Sept 95
  - Transmission Media, Comparative Evaluation of: CS Dec 230
- Community-Industry-School Relations, Experiment in: E Sep 113
- Compactness in Mobile Radio-Telephone Design: VC Sep 64
- Company, Engineering Department Organization in a Small: EM Jun 41
- Compass, Radio, Testing with Small Shielded Enclosures: ANE Mar 4
- Complex-Curve Fitting: AC May 37
- Components:
  - Application Program: CP Sep 190
  - Army Research Program: CP Sep 193
  - Automatic Testing of: PT Sep 1
  - Future Trends of: CP Sep 144
  - Improvements During Past Ten Years: CP Sep 210
  - Part Insertion Machine, Punched-Card-Controlled: PT Aug 93
  - Parts, Future, for Mechanization: PT Aug 17
  - Parts for Mechanized Assembly, Modular Dimensioning of: PT Aug 12
  - Production Problems Relating to the Power-Carrying Capacity of a *K*-Band Microwave: PT Jun 29
  - Reliability Problems, Long-Term: CP Jun 62
  - Screening Procedures: CP Dec 252
  - For Submarine Telephone Cable Repeaters: CP Mar 34
  - Switching, for Controlled Fusion Research: NS Sep 23
  - Tester, Semiautomatic Circuit: PT Sep 12
- Computational Aspects of Brain Function: ME Sep 164
- Computation, Instrument Servos for General Purpose: IE Apr 1
- Computation, Reducing Time in the Analysis of Networks by Digital Computer: CT Mar 136; Correc: Dec 394
- Computers:
  - Analog, Anticipatory Display Design Through the Use of: ANE Dec 228
  - Analog-Digital, for Simulation: EC Jun186
  - Analog, for Finding an Optimum Route Through a Communication Network: CS May 37
  - Analog, Generalized Integration on: EC Jun 210
  - Analog, Optimization by Random Search on: EC Jun 200
  - Analog, Perturbation Technique for: EC Jun 218
  - Applied to Ballistocardiography: ME Sep 109
  - Arithmetic Operations Using a Modified Reflected Binary Code: EC Dec 449
  - Control, Optimal: AC Dec 111
  - Control Systems, Mathematical Models for: AC Dec 80
  - Cores, Metallic Tape, Nondestructive Readout of: EC Dec 470
  - Digital, Microwave Filter Design Using: MTT Jan 99
  - Digital Recording of Electrocardiographic Data for Analysis by: ME Sep 167
  - Digital, for Terminal-Area Air Traffic Control: SET Jun 66
  - Entry of Flight Test Data: SET Sep 123
  - Equipment Construction, Airborne Digital: PT Jun 18
  - Error-Correcting, Having Only an Error-Detecting Part: EC Sep 321
  - Microwave, Logic Design for: EC Sep 271
  - Microwave, Semiconductor Parametric Diodes in: EC Sep 287
  - Microwave, History and Introduction: EC Sep 263
  - Microwave, ONR Symposium on: EC Sep 262
  - MUSASINO-1, Parametron Digital: EC Sep 308
  - Operation, Cooling Air Flow During: CP 180
  - Program, Topological Network Analysis as a: CT Mar 135
  - Reducing Computation Time in the Analysis of Networks by Digital: CT Mar 136; Correc Dec 394
  - U. S., Russian Visit to: EC Dec 489
- Computing Technique, CORDIC Trigonometric: EC Sep 330
- Conductance of Dipoles of Arbitrary Size and Shape: AP Oct 353
- Cones:
  - Radiation from Ring Sources in Presence of: AP Apr 168
  - Radiation from Slot Arrays on: AP Jul 213
  - Surface for a Prescribed Radiation Pattern, Current Distribution over a, Correction to: AP Jan 104
  - Two Infinite, Capacitance of: AP Jan 102
  - Wedge Surfaces with Varying Surface Impedance, Properties of: AP Dec S231
- Confidence Interval on Predicted System Reliability, Forming a: RQC Jun 64
- Connectors, Printed Wire, Analysis of: CP Sep 223
- Contact Closures, Circuits for High-Speed Checking of: I Sep 51
- Contracting, Group: EM Sep 71
- Control:
  - Adaptive Flight: AC Dec 113
  - Attitude, of Space Vehicles: AC Dec 34
  - Digital, First Yugoslav Machine Tool with: IE Jul 40
  - Guidance System for Discoverer: MIL Oct 184
  - of the Human Environment: AC Dec 36
  - Impact of Information Conversion on: AC Dec 21
  - Industrial, Aspects of Magnetic Recording Useful for: IE Dec 53
  - and Information in Organ Systems: ME Mar 23
  - and Machinery Systems Laboratory, Combined: E Sep 128
  - Numerical, for Automatic Manufacturing in General Industry: IE Jul 33
  - Optimal Computer: AC Dec 111
  - Path, Tracking and: AC Dec 35
  - Processes, Adaptive: AC Nov 1
  - Processes, Adaptive, Dynamic Programming Approach to: AC Nov 10
  - Reaction Wheel Attitude, for Space Vehicles: AC Dec 139
  - Synthesis, Pendulous Velocity Meter: AC Dec 60
  - Techniques, Nonlinear, Employed by a Biological Control System: AC Dec 45
  - Theory Based on Methods of Lyapunov: AC Dec 20
- Controlled Propulsion: AC Dec 30
- Control Systems:
  - Adaptive, Parameter Tracking Servo for: AC Nov 100
  - Amplifier Response, Effect of Power Source Regulation on: AC Dec 59
  - Analysis Via Method of Lyapunov: AC Dec 112
  - Automatic, *D*-Decomposition Analysis of: AC Dec 150
  - Automatic Flight, Electronic Memory in: AC Dec 128
  - Automatic Flight, Gain Control in: AC Dec 116
  - Automatic Flight, Pulse Controlled Integration in: AC Dec 133
  - Automatic Linear Feedback: AC Dec 5
  - Automatic Temperature, for Fluid Dynamics Facility: AC Dec 81
  - Bibliography, Adaptive of Self-Optimizing: AC May 65
  - Bi-Stable: AC Dec 46
  - Computer, Mathematical Models for: AC Dec 80
  - Digital, Present and Future: IE Dec 44
  - General Theory of: AC Dec 20
  - Manual, Characteristics of Human Operator in: AC May 44
  - Multipole, Optimum Synthesis of: AC Nov 212
  - Nonlinearities, Spectral Characterization of: AC Dec 199
  - Nuclear Reactor: IE Jan 38
  - Problems, Zeros of Functions in: AC Dec 197
  - Sampled-Data, with Time-Varying Sampling Rate: AC May 15
  - Solid-State Automatic Flight: AC Dec 114
  - Synthesis of Multipole, with Random Inputs: AC Dec 212
  - Third Order Contactor, Synthesis of: AC Dec 109
- Converter, Analog to Digital: EC Mar 31
- Cooling Air Flow During Computer Operation: CP Sep 180
- Cooling Rates of Plate Materials in Vacuum: ED Jan 119
- CORDIC, Decimal-Binary Conversions in: EC Sep 335
- CORDIC Trigonometric Computing Technique: EC Sep 330
- Cornea, Plastic: ME Mar 43
- Correlation:
  - and Delay Line Attenuation: IT Mar 4
  - Function, An Inequality Concerning the Envelope of: IT Mar 33
  - Function and Power Spectra of Radio Links: AP Apr 137
  - Interchannel, in Parallel Filters: IT Sep 106
  - Sign, Rectangular Wave Functions and the Concept of: I Mar 36
- Cost, Designing Standard Assemblies for Minimum Manufacturing: PT Jun 4
- Cost, Research and Development, Estimation: EM Mar 8
- Costs, Minimizing Production, Through Modular Automatic Test Equipment: IE Apr 29, PT Sep 19
- Counter, Transistor-Driven Beam Switching Tube Decade: NS Dec 16
- Counters, Boron-Lined Proportional, Effects of Nuclear Reactor Exposure on: NS Dec 1
- Counting Tube Read-Out Technique, Glow: EC Sep 317
- Coupler, Image Line: MTT Jul 391
- Coupler, Optimum Multi-Branch Waveguide, Design of: MTT Oct 466
- Couplers, Mode, and Multimode Measurement Techniques: MTT Jan 110

- Coupling, Aperture-to-Medium, on Line-of-Sight Paths: Fresnel Scattering: AP Apr 142
- Coupling of Propagating Structures, Periodic: Jul 325
- Crash Position Indicator for Aircraft: ANE Sep 222
- Cross Correlation Between Noisy Channels: IT Jun 77
- Crosspoint Number, A Limit of: CT May 187; IT May 187
- Crosscorrelation and Autocorrelation Analysis in Electroencephalography: ME Sep 179
- Cross-Spectrum Analyzer, Analysis of Electroencephalograms by: ME Sep 149
- Crystal Diodes and Barretters, Deviations from Square Law for: I Dec 103
- Crystal Mixers, Delay Distortion in: MIT Apr 247

  - Processing, in Bits and Pieces: EC Jun 118
  - Processing, Coherent Optical: AC Nov 137
  - Processing, Frequency Domain Applications to: SET Mar 33
  - Processing, New Magnetic Recording Techniques for: IE Dec 47
  - Recording Systems, Figure of Merit for: EC Mar 48
  - Systems, Integrated, Impulsing of Linear Networks in: CS Sep 189
  - Transmission, High-Speed, Synchronization of Single-Sideband Carrier Systems for: CS Jun 110
  - Transmission System, Real Time: CS Sep 201
- Decay Exponents and Diffraction Coefficients for Surface Waves: AP Dec S52
- Decimal-Binary Conversions in CORDIC: EC Sep 335
- Decipherability, Unique: IT Sep 98
- Decision-Making and Measurement, Profitability Criterion for: EM Sep 65
- Deflection:
  - Oscillators for Television Receivers: BTR May 33
  - Output and Driver Stages, Transistor Vertical: BTR May 7
  - System, The Fuse in the Horizontal: BTR Jan 10
  - System, Transistorized Class "B" Vertical: BTR Dec 20
  - Tube, Sheet-Beam, Audio Applications of: BTR Dec 3
- Delay Distortion in Crystal Mixers: MTT Apr 247
- Delay Lines:
  - and Correlation Line Attenuation: IT Mar 4
  - Design of Filter, in Solenoidal Form: CT Dec 386
  - Magnetostrictive: UE Feb 16
  - Periodic Filters, Analysis and Synthesis of: CT Sep 325
  - Specifications for Matched-Filter Communciations Systems: CP Dec 263
- Delay Networks, Maximally-Flat: CT Jun 235
- Delta Modulation for Cheap and Simple Telemetering: SET Dec 205
- Delta Sound System for Television Receivers: AU Jan–Feb 16
- Demodulating Compensating Networks: AC Dec 71
- Detection:
  - of Asymmetric Sideband Signals in the Presence of Noise: BTR Jan 46
  - Improvements in, Gain-Control, and Audio-Driver Circuits of Transistorized Broadcast Receivers: BTR Dec 46
  - by a Radar, First Probability of: IT Mar 9
  - Sequential, Experimental Results in: ET Jan 41
- Detectors:
  - External Radioisotope, Measurement of Branched Flow by: ME Dec 287
  - Helium Leak, Correction to Ultrasensitive Techniques Employing: ED Jan 118
  - Quasi-Peak to Measure of Probability Density Function: I Mar 19
  - with Specified Time Constants, Design of Quasi-Peak: RFI May 18
- Determinant Relating to Cascaded Circuits: CT Mar 134
- Dictator, How to Become: EWS Jun 42
- Dielectrics:
  - Capacitors, Plastic: CP Jun 114
  - Filled Periodic Structures, Experimental Determination of Wavelengths in: MTT Oct 480
  - Image Lines at Millimeter Wavelengths: MTT Jan 65
  - Inorganic: CP Mar 3
  - Interfaces, Slotted, Properties of: AP Jan 62
  - Plates, Parallel, Matching of to Free Space: AP Dec S288
  - Propagation Constants in Waveguide Partially Filled with: MTT Apr 294
  - Rod, Terminal Admittance of: AP Jul 207
- Differential:
  - Amplifiers, Transistor Temperature Analysis for: I Dec 82
  - Analyzer for Finding Roots of Polynomials: EC Jun 182
  - Analyzer Simulation, Linear System Approximation by: EC Jun 204
  - Analyzers, Digital, Systematic Scaling for: EC Dec 486
- Diffraction:
  - Coefficients and Decay Exponents for Surface Waves: AP Dec S52
  - by Discs and Strips, Equations for High-Frequency: AP Dec S37
  - by a Half-Plane with a Special Impedance Variation: AP Dec S88
  - Diffraction of Nearly Plane Waves by 45° and 90° Conduction Wedges: AP Dec S2884
  - of a Plane Wave by a Funnel-Shaped Screen: AP Dec S71
  - and Refraction of Pulses: AP Dec S78
  - Scalar, by an Elliptic Cylinder: AP Dec S21
  - of Scalar Waves by a Circular Aperture: AP Dec S12
  - in the Shadow Region, Computing Knife Edge: AP Apr 198
  - by Smooth Conical Obstacles: AP Dec S226
  - by Surfaces of Variable Curvature: AP Dec S68
  - Theory, Infinite Integral Transforms in: AP Dec S7
  - Theory of Tropospheric Propagation Beyond the Radio Horizon: AP Jul 261, 268
- Diffusion of Oxygen and Carbon Dioxide Through Teflon Membranes: ME Mar 54
- Digital Circuit Design, Boolean Matrix Equations in: EC Jun 131
- Digital Control, First Yugoslav Machine Tool with: IE Jul 40
- Digital Control Systems—Present and Future: IE Dec 44
- Digital Data Acquisition System, Airborne: SET Sep 117
- Digital Differential Analyzers, Systematic Scaling for: EC Dec 486
- Digital Filter, Noise Power of an Optimum Linear: IT Jun 58
- Digital Frequency Modulation Systems, Minimum Bandwidth, Using Gaussian Filtering: CS Dec 284
- Digital Magnetic Circuits and Materials, Bibliography of: EC Jun 148
- Digital Operational Flight Trainer, Multiple-Cockpit: EC Sep 326
- Digital Phase-Modulation Communication Systems: CS May 3
- Digital Recording of Electrocardiographic Data for Analysis by a Computer: ME Sep 167
- Digital Selective Signaling System for Mobile Radio: VC Apr 74
- Digital System for Position Determination: SET Mar 42
- Digital Systems, Parametric Phase-Locked Oscillator Applications to: EC Sep 277
- Diodes:
  - Amplifiers and Pulse Modulators: ED Jul 341
  - Crystal, and Barretters, Deviations from Square Law for: I Dec 103
  - Microwave Logic Circuits Using: EC Sep 302
  - Parallel-Plane, Effect of Secondary and Backscattered Electrons in: ED Oct 413
  - Parametric, Equivalent Circuits of: BTR Dec 83
  - Point Contact, in Terms of *P-N* Junction Theory: ED Jul 270
  - Propagation of Space-Charge Waves in Drift Spaces and: ED Apr 225
  - Semiconductor, Bidirectional Transmission Gate Using: EC Dec 498
  - Semiconductor Parametric, in Microwave Computers: EC Sep 287
  - Silicon, Rating and Application Considerations for: CP Dec 269
- Diplexing Filter, High Power: MTT Jul 384
- Dipoles:
  - Antenna Coupled to a Two-Wire Transmission Line: AP Oct 386
  - of Arbitrary Size and Shape, Conductance of: AP Oct 353
  - Arrays, Long End-Fire, Calculated Phase Velocity of: AP Dec S424
  - Pulsed, in an Interface; Field of: AP Dec S87
  - Rectangular Loop Antenna as: AP Jan 53
- Directivity of Broadside Array of Isotropic Radiators: AP Apr 197
- Discontinuity Problem at the Input to and Anisotropic Waveguide: AP Dec S261
- Discoverer, Guidance and Control System for: MIL Oct 184
- Discriminator Calibrator, Use of Multivibrator Counter in the Design of: SET Sep 131
- Discriminator, Dynamic Analysis of the Averaging Type FM: SET Sep 111
- Dispenser Cathode Magnetrons: ED Jan 115
- Display Design, Anticipatory, Through the Use of an Analog Computer: ANE Dec 228
- Distance Functions, Ambiguity and, Invariant Relations for: IT Dec 164
- Distortion, Nonlinear, Reduction by Complementary Distortion: AU Sep–Oct 128
- Diversity Reception, Angular, at 2290 MC: CS Sep 195
- Dogs, Measurements of Cardiac Output in, by Implanted Electromagnetic Flowmeter: ME Dec 210
- Doppler Phenomena in Space Communications: CS May 25
- Doppler Shift, Relativistic Consideration of: ANE Mar 37
- Doppler Shift of Satellite Emissions: AP Jan 99
- Double-Sideband Suppressed-Carrier Multiple Equipment: CS Jun 92
- Drift Tubes and Helices, Plasma Frequency Reduction in Electron Streams by: ED Oct 468
- Driving-Point Admittances, RC Constant-Argument: CT Sep 310

Great Britain, Microwave Advances in 1958: MTT Jul 325
Greeks, The, Had a Word For It: EWS Dec 73
Ground-Controlled Approach, Development of: ANE Jun 71
Ground-Controlled Automatic Approach System: ANE Jun 142
Ground Wave Pulse, Propagation of: AP Jan 1
Group Contracting: EM Sep 71
Guidance and Control System for Discoverer: MIL Oct 184
Guidance, Non-Real-Time Simulation of SAGE Tracking and BOMARC: EC Mar 36
Guide, Transmission Characteristics of: AP Dec S183
Guided Waves and Radiation: AP Dec S191
Guided Waves on Sinusoidally-Modulated Reactance Surfaces: AP Dec S201
Guiding of Waves by Uniformly Rough Surfaces: AP Dec S154
Gun and Focusing System for Crossed-Field Traveling-Wave Tubes: ED Jan 18
Gyrator and Isolator, Wide-Band, Nonreciprocal TEM-Mode Structure for: MTT Oct 453
Gyro-Drift Measurement, Single-Axis Floated, Automation of: PT Aug 51
Gyrovibrator: ANE Mar 16

H

Harmonic Analysis of Frequencies in Pulsatile Blood Flow: ME Dec 291
Harmonic Exponentials to Identify Nonlinear Operators: AC Nov 91
Harmonic Power Generated by Microwave Transmitters, Measurement of: MTT Jan 116
Heart Electrical Activity, Display of: ME Sep 116
Heart Potentials, Multichannel Analyzer for: ME Sep 107
Height-Gain Curves Taken Over Rough Terrain: AP Oct 405
Helical Antenna, Elliptical, Field of: AP Jan 46
Helical Antennas, Bandwidth of: AP Dec S379
Helical Array Elements, Short, Complex Mutual Impedance Between: AP Jul 279
Helices and Drift Tubes, Plasma Frequency Reduction in Electron Streams by: ED Oct 468
Helicopter Operational Flight Trainer: MIL Jul 82
Helium Leak Detector, Correction to Ultrasensitive Techniques Employing: ED Jan 118
Helix, Application of the Contrawound: ED Apr 195
Helix, Impedance and Dispersion Characteristics of Flattened: ED Apr 189
Helix Waveguides, Transmission of TE_{01} Wave in: MTT Jul 370
Helmholtz Equation, Asymptotically Expansible Solutions of: AP Dec S475
Helmholtz's Theorem in Finite Regions: AP Dec S119
H-Guide, Mode Attenuation in: MTT Oct 480
Hot Gas Servo Design: AC Dec 97
Human Body, Telemetering from Within the: ME Jun 100
Human Disorientation Device Simulating Angularly-Accelerated Motion: MIL Jul 99
Human Environment, Control of: AC Dec 36
Huygens Principle, New Forms of: AP Dec S103
Hydrodynamics as Applied to the Living Cardiovascular System: ME Dec 252; Discussion of: ME Dec 266
Hypodermic Needles, Ultrasonic Cleaner for: UE Feb 3
Hysteresis, Minimizing, in a Ferrite Variable Attenuator: MTT Apr 295
Human Link in an Automatic Control System: ME Sep 125
Human Operator in Manual Control Systems, Characteristic of: AC May 44

I

Illustrations, Planning, First, Simplifiers Writing Later: EWS Jun 56
Imaginary Part, Constant, Network Functions with: CT Dec 370
Image Intensification, Fluoroscopic, Applications of: ME Jun 75, 78, 82
Image Line Coupler: MTT Jul 391
Image Lines, Dielectric, at Millimeter Wavelengths, MTT Jan 65
Image Parameter Square-Frequency Filter Design: CT Jun 208
Impedance:
  Characteristic, of Split Coaxial Line: MTT Jul 393
  Complex Mutual, Between Short Helical Array Elements: AP Jul 279
  with Negative Real Parts, Representation of: MTT Oct 475
  Parameters in a Coupled Antenna System, Approximation of: AP Oct 373
  Properties of Complementary Multiterminal Planar Structures: AP Dec S371
Impulse Train Approximation for Time-Varying Linear System Synthesis in the Time Domain: CT Dec 393
Impulsing of Linear Networks in Integrated Data Systems: CS Sep 189
Incidence Angle, Dependence of Reflection on: MTT Oct 423
Indicator, Beam-Profile: NS Jun 64
Industrial Electronics, Applying Military Reliability Research to: IE Dec 34
Industrial Electronics, Frontiers in: IE Jul 2
Industrial Instrumentation, Infrared Techniques in: IE Dec 15
Industry:
  Advanced Education in: E Jun 73
  Community-School Relations, Experiment in: E Sep 113
  Contribution and Needs in Graduate Education: E Apr 38, Jun 128
  University Cooperation in Research: EM Mar 12
  View of Electronic, by Investment Capital: EM Mar 1
Inertial Navigation, Vector Principles: ANE Sep 159
Inertial Reference, Nongyroscopic: AC Nov 182
Information:
  Administering, Input and Output in Research Laboratories: EM Jun 55
  and Control in Organ Systems: ME Mar 23
  Conversion on Control, Impact of: AC Dec 21
  or Data: IE Apr 35
  Entropy Functionals, Direction of Change for: IT Dec 184
Infrared Techniques in Industrial Instrumentation: IE Dec 15
Insertion Loss in Feedthrough Capacitors: RFI May 11
Insertion Machine, Punched-Card-Controlled Component-Part: PT Aug 39
Instrument Landing:
  Approach Systems, Survey of: ANE Jun 78
  Early Systems: ANE Jun 67
  FAA Program of: ANE Jun 112

  Improvements: ANE Jun 85
  National Bureau of Standards Work: ANE Jun 61
Instrumentation in Medical Research: ME Jun 63
Integrated Data Systems: CS Jun 95
Integrated Devices Using Direct-Coupled Unipolar Transistor Logic: EC Jun 98
Integration, Generalized, on the Analog Computer: EC Jun 210
Integrator Circuit, Simplified Logarithmic: NS Jun 74
Interfaces, Waves on: AP Dec S140
Interference:
  FM, and Noise-Suppression Properties of the Oscillating Limiter: VC Sep 37
  Identifying, Using a Tunable Receiver and a Panadapter: VC Apr 13
  Intermodulation Products Generated in Mobile Transmitters: VC Sep 16
  Microwave, Control of: RFI May 1
  Prevention: VC Sep 4
Interferometers:
  Broad-Band Radio Frequency: I Sep 39
  Fabry-Perot, Reflectors for: MTT Apr 221
  Measurements of Plasma Density Fusion Experiments: NS Sep 20
  Synthesis of Large Radio Telescopes by Use of: AP Dec S120
Interferometry in Extraterrestrial Metrology: SET Dec 186
Intermediate Frequency Stabilization by Regenerative Frequency Conversion: I Mar 32
Intermodulation Products Generated in Mobile Transmitters, Interference Caused by: VC Sep 16
Interplanetary Communication System: SET Dec 196
Instrumentation and Range Safety System for Vandenberg Air Force Base: SET Mar 14
Invariant Relations for Ambiguity and Distance Functions: IT Dec 164
Investment Capital, View of Electronic Industry by: EM Mar 1
Ion Densities in Gases, Electrometer Measurements of Very Low: I Sep 46
Ionic Propulsion Systems, Problems in: MIL Apr 27
Ionized Gases, Propagation of Electromagnetic Waves in: AP Dec S340
Ion Phase Measurement Techniques on the Birmingham Cyclotron: NS Mar 35
Ion Plasma Oscillations, Theoretical Study of: ED Oct 372
Ionospheric Multipath Distortion, Pulse Phase-Change Signaling in the Presence of: CS Jun 102
Ionospheric Ray Tracing Technique: AP Oct 393
Ionosphere, Electron Densities of, Utilizing Rockets: AP Oct 414
IRE and Secondary School Cooperation: E Jun 67
IRE Section Bulletins: EWS Jan 34
Isolator, Ferrite Load: MTT Jan 174
Isolator and Gyrator, Wide-Band, Nonreciprocal TEM-Mode Structure for: MTT Oct 453
Isothermal Blood Flow Velocity Probe: ME Dec 283
Isotropic Radiators, Directivity of Broadside Array of: AP Apr 197

J

Japan, Microwave Advances in 1958: MTT Jul 331
Junctions:
  Diffused, Space-Charge Layer Width in: ED Oct 405
  RN Theory, Point-Contact Diodes in Terms of: ED Jul 270
  Reactive Effects in Forward Biased: ED Jul 330
  Triodes, Maximum Switchable Power Density in: ED Jul 322
  Variable Capacitor, Design of High Frequency *p-n:* ED Jul 347

K

Kidney, Extracorporeal Artificial: ME Mar 7
Knife Edge Diffraction in the Shadow Region, Computing: AP Apr 198
Klystrons:
  Amplifiers, Low-Noise: ED Oct 428
  Effect of Space Charge on Bunching in: ED Jan 54
  Frequency Multiplier for Millimeter Waves: ED Apr 236
  Multicavity, Small-Signal Theory of: ED Oct 449

L

Laboratories, Undergraduate, and Efficient Use of Students' Time: E Jun 75
Laboratory, Combined Machinery and Control Systems: E Sep 128
Laboratory in Engineering Education, Role of: E Mar 23
Laboratory, Its Scope and Philosophy: E Sep 120
Ladders, Maximally-Flat Time Delay: CT Jun 214
Laguerre Polynomials for Treating Envelope and Phase Components of Gaussian Noise: IT Sep 102
Landing Systems:
  Aids for Carrier Aircraft: ANE Jun 95
  All-Weather: ANE Jun 75
  Automatic: ANE Jun 128
  Instrument Approach and, FAA Program of: ANE Jun 112
  REGAL Approach and: ANE Jun 115
Lathe, An Automatically Controlled Vertical Turret: IE Apr 19
Legal Considerations in Presenting Technical Information: EWS Dec 84
Lenses, Application of Non-Symmetrical Electron, to TV Image Reproduction: BTR Dec 54
Lenses, Spherically Symmetric: AP Jan 32
Lenses, Spherically Symmetric, Generalizations of: AP Oct 342
Libraries, Technical, in the Boston Area: EWS Jun 52
Limiter, Oscillating, FM Interference and Noise-Suppression Properties of: VC Sep 37
Limiters, Ferrite Microwave, Characteristics of: MTT Jan 18
Limiters, Signal-to-Noise Ratios in Smooth: IT Jun 79
Linear Systems, Network Theory and Its Relation to the Theory of: AP Dec S435
Logarithmic Amplifier Design: I Dec 91
Logarithmic Integrator Circuit, Simplified: NS Jun 74
Logic:
  Circuit, Generalized Resistor-Transistor: EC Mar 8
  Circuits, Fast Microwave: EC Sep 297
  Circuits, Microwave, Using Diodes: EC Sep 302
  Circuits, Resistance-Coupled Transistor, DC Design of: CT Sep 304
  Design for a Microwave Computer: EC Sep 271
  Dual Polarity as a Design Tool: EC Jun 227
  Integrated Devices Using Unipolar Transistor: EC Jun 98
  Magnetic Core, in Card-to-Tape Converter: EC Jun 169
  Nanosecond, by Amplitude Modulation at *X* Band: EC Sep 265
Logical Machine Design Bibliography: EC Sep 367
Logical Machines, Information-Lossless Finite-State, Canonical Forms for: CT May 41; IT May 41
Logistic Planning, Failure Rate Data in: RQC Jun 41
Loops, Phase-Locked, Linear Design of: SET Dec 166
Loudspeakers, Performance of Enclosures for Low-Resonance: AU Jan–Feb 5
Loudspeakers, Phase Shift in: AU Sep–Oct 120
Luminescence, Magnetron Cathode Arm Radiation and: ED Apr 242, Oct 468
Lunar Exploration, Manned, Rocket for: SET Dec 155
Lyapunov, Control System Analysis Via Method of: AC Dec 112
Lyapunov, Control Theory Based on Methods of: AC Dec 20

M

Machinery and Control Systems Laboratory, Combined: E Sep 128
Machines, Minimal Sequential: EC Sep 339
Machine, Minimal-State, Reduction of a Machine to: EC Sep 346
Machines, Minimal State, Synthesis of: EC Dec 441
Machine Recognition of Hand-Sent Morse Code: IT Mar 17
Machine Tool with Digital Control, First Yugoslav: IE Jul 40
Magnetostrictive Delay Lines: UE Feb 16
Magnetic Alloys, Recent Developments in: CP Jun 119
Magnetic Auditory Stimulation by Magnet Fixed to Eardrum: ME Mar 22
Magnetic Circuits and Materials, Bibliography of Digital: EC Jun 148
Magnetic Core Logic in Card-to-Tape Converter: EC Jun 169
Magnetic-Core Memory, Diode-Steered: EC Dec 474
Magnetic Fields of Square-Loop Thin Films: EC Dec 458
Magnetic Tape Recording:
  with Longitudinal or Transverse Oxide Orientation: AU May–Jun 76
  Null Method of Alignment in: AU Sep–Oct 166
  Techniques, New for Data Processing: IE Dec 47
  Useful for Industrial Control, Aspects of: IE Dec 53
Magnetism and the Rare-Earth Metals: CP Jun 93
Magnetron Cathode Arm Radiation and Luminescence: ED Apr 242, Oct 468
Magnetrons, Dispenser Cathode: ED Jan 115
Mail, Automatic, Cancelling and Facing, Electronics in: IE Apr 14
Mammals, Investigation of Thermal Balance by Microwave Radiation: ME Jun 66
Management:
  Control of Professional Operations: EM Sep 81
  Development, Forward Look at: EM Mar 19
  of Research and Development: EM Sep 75
  Study on Parts Specifications, for Reliability: CP Sep 128
  Views Automation: IE Jan 59; PT Sep 35
  Weapons Systems: MIL Jan 19
  Weapon System, and Systems Engineering: MIL Jan 4
Man-Machine Systems, Research and Development for: PT Aug 23
Manufacture of Microwave Structures and Mechanical Design: MTT Oct 402
Manufacturing Cost, Designing Standard Assemblies for Minimum: PT Jun 4
Manufacturing in General Industry, Numerical Control for Automatic: IE Jul 33
Manufacturing System, Numerically Controlled: IE Jan 2
Markoff Envelope Process: IT Sep 139
Markoff Envelope Process, Further Comments on: IT Dec 187
Maser, Solid-State, Physics of: CD Jun 81
Maser, UHF Solid-State: MTT Jan 92
Matching of Parallel Dielectric Plates to Free Space: AP Dec S288
Material Development, Influence on Transformer Design: CP Sep 201
Materials, an Industry-Wide Problem: CP Sep 175
Mathematical Models for Computer Control Systems: AC Dec 80
Matrices:
  Cut-Set of Tie-Set, How to Grow Your Own Trees from: CT May 110
  Orthogonal, Error-Correcting Codes and Matrix Switches: EC Sep 400
  in Theory of Autonomous Sequential Networks: CT Dec 392

    Telephone System, New Manual: VC Sep 73
    Telephone, Transistorized Selector Device for: VC Apr 71
    Transmitters, Interference Caused by Intermodulation Products: VC Sep 16
Mode Attenuation in the *H*-Guide: MTT Oct 480
Mode Couplers and Multimode Measurement Techniques: MTT Jan 110
Modes in Rectangular Waveguides Partially Filled with Transversely Magnetized Ferrite: AP Dec 471
Mode Theory of Lossless Periodically Distributed Parametric Amplifiers: MTT Jul 360
Modular Automatic Test Equipment, Minimizing Production Costs Through: IE Apr 29; PT Sep 19
Modular Dimensioning of Component Parts for Mechanized Assembly: PT Aug 12
Modulation:
    Angle, by a Mixture of a Periodic Function and Noise: IT Sep 140; Correc: IT Dec 186
    Delta, for Cheap and Simple Telemetering: SET Dec 205
    Pulse Code, Telemetry, Standards for: SET Dec 194
    Systems, Minimum Bandwidth Digital Frequency, Using Gaussian Filtering: CS Dec 284
    Techniques, Factors Affecting, for VHF Scatter Systems: CS Jun 77
Modulator, Single-Sideband, Ferrite Half-Wave for: MTT Apr 295
Modulators, Pulse, Semiconductor Diode Amplifiers and: ED Jul 341
Module Prediction: RQC Jun 53
Molding, Small Parts, Potting, Encapsulating and: PT Aug 50
Molecular Oscillator and Amplifier, Tunable Millimeter Wave: MTT Apr 268
Monitor, A Stack Effluent Radioisotope: NS Dec 20
Morse Code, Machine Recognition of Hand-Sent: IT Mar 17
Morse Distribution: IT Mar 25
Motivation, Engineering, 1200 Case Studies of: E Jun 82
Motor Carrier Mobile Radio Systems: VC Sep 24
Multicouplers Employing Minimum-Lose Filters, Tunable Passive, Correction to: MTT Jul 369
Multicouplers, Tunable Passive, Employing Minimum-Loss Filters: MTT Jan 121
Multipath Distortion, Effect on the Choice of Frequencies for High Frequency Communication: AP Oct 397
Multipath, Equipment to Reduce Teleprinter Errors in the Presence of: CS Sep 185
Multipath Protection in Meteor Burst Communications: CS Sep 209
Multiplex Equipment, Double-Sideband Suppressed-Carrier: CS Jun 92
Multiplex Error in FM/FM and PAM/FM/FM Telemetry: SET Sep 138
Multiplexers, Waveguide, Strip Transmission Line and: MTT Oct 475
Multiplexing, Power-Division, in Frequency Modulation: CS Sep 147
Multiplexing, Time, Applied to Analog Computation: EC Mar 42
Multiplication for Complement Codes, A Ring Model for: EC Mar 25
Multiplier, Four-Quadrant: EC Jun 222
Multiplier, Klystron Frequency, for Millimeter Waves: ED Apr 236
Multiplying and Function Generation, Position and Velocity Servos for: EC Sep 391
Multivibrator Counter in the Design of Discriminator Calibrator, Use of: SET Sep 131
Muscle Activity, Computation of, from the Integrated Electromyogram: ME Sep 119
Muscle Rigidity, Strength and Tremor, Method of Measuring: ME Sep 159
Musical, Instruments and Orchestras, Amplitudes and Spectra of: AU May–Jun 47

N

Nanosecond Logic by Amplitude Modulation at *X* Band: EC Sep 265
Nanosecond Pulse Transformers: NS Mar 26
Navigation:
    Inertial, Vector Principles of: ANE Sep 159
    Space, Application of Gravitation Field to: SET Mar 47
    Systems, Principles of: ANE Dec 221
    Trainer, Celestial: MIL Jul 69
Near Field Analysis, New Method of: AP Dec S458
Negative-Impedance Conversion Methods of Active RC Synthesis: CT Sep 296
Negative Resistance Amplifiers, Noise Measurement of: I Sep 44
Negative Resistance Device, Nesistor Semiconductor: ED Jul 278

- Permeability Matrix for a Ferrite: MTT Jan 176
- Personnel Turnover and Replacement: EM Jun 49
- Perturbation Technique for Analog Computers: EC Jun 218
- Phase Equalization, Problem of: CT Sep 272
- Phase-Locked Loops, Linear Design of: SET Dec 166
- Phase-Modulation Communication System Digital: CS May 3
- Phase Plane Analysis of Nonlinear Time-Varying Systems: AC Nov 80
- Phase Plane Analysis in Quantized Systems: AC Nov 43
- Phase Shift in Loudspeakers: AU Sep–Oct 120
- Phase Shifter, Ferrite, for UHF: MTT Jan 27
- Phase Shifters, Ferrite, Precise Control of: MTT Apr 229
- Phase Velocity, Calculated, of Long End-Fire Dipole Arrays: AP Dec S424
- Phase Velocity of Propagation Along Yagi Structure: AP Jul 234
- Phonograph Cartridges, Stereo, Two-Channel Ceramic Transducer for: AU Jul–Aug 96
- Photography, Electronic: IE Dec 26
- Physics Course in Arizona Engineering Curriculum: E Sep 117
- Physiological Considerations of Respiration: ME Mar 24
- Physiological Information, Short-Distance Telemetering of: SET Jun 82
- Picture Display with Low Drive Signals, Electron Gun for: ED Oct 377
- Pictures, Probabilistic Model for Run-Length Coding of: IT Dec 157
- Pinch Process, Electromechanical Energy Conversions in a Cylindrical: SET Jun 55
- Pioneer IV, Tracking of: SET Dec 196
- Planar Structures, Complementary Multiterminal, Impedance Properties of: AP Dec S371
- Plasma:
  - Density in Fusion Experiments, Interferometer Measurements: NS Sep 20
  - Disturbances in a Multi-Velocity: ED Apr 231
  - Frequency Reduction in Electron Streams by Helices and Drift Tubes: ED Oct 468
  - Gas-Discharge, Interaction of Microwaves with: MTT Jan 69
  - Oscillations, Ion, Theoretical Study of: ED Oct 372
  - Physics, Contemporary: SET Dec 162
  - Propagation Through a Hypersonically Produced: AP Jul 240
  - Propulsion Devices for Space Flight: MIL Apr 34
  - Propulsion Possibilities: MIL Apr 42
- Plastic Cornea: ME Mar 43
- Plastic Dielectric Capacitors: CP Jun 114
- Plastics, Use in Medicine: ME Mar 52
- Pocket Receiver, A VHF: VC Sep 20
- Poincaré Metric Reliability of Switching Components: IT Sep 137
- Poles:
  - Determinations with Complex-Zero Inputs: AC Nov 150
  - High Order, Evaluating Residues and Coefficients of: AC Nov 132
  - Migration in Coupled-Resonator Filters: CT Mar 95
  - Zero Concepts in Sampled-Data Systems: AC Dec 173
  - and Zeros, Specified, Synthesis of Feedback Systems with: AC Dec 185
- Polystrip Flat-Wire Cables, Designing with: PT Aug 28
- Position Information Using Simultaneous Range Measurements: ANE Sep 111
- Positive Real Function, Generalizations of the Concept of: CT Dec 374
- Potentiometers, Metal and Oxide Film: CP Jun 105
- Potter Electroturbinometer: ME Dec 270
- Potting, Encapsulating, and Small Parts Molding: PT Aug 50
- Power Source Regulation on Control System Amplifier Response, Effect of: AC Dec 59
- Power Theorem on Absolutely Stable Two-Ports: CT Jun 159
- Power, Transistorized, Supplies for Higher Input Voltages: VC Apr 54
- Prediction, Module: RQC Jun 53
- Prediction Using Network Theory Concepts, Nonstationary Smoothing and: CT May 1; IT May 1
- Pressure Regulator, Automatic, for Extracorporeal Circulation: ME Sep 184
- Primate Behavior, Automatic Recording of Digital Data in the Analysis of: ME Sep 121
- Printed Circuits, Topology of: CT Dec 390
- Printed Wire Connectors, Analysis of: CP Sep 223
- Printed Wiring, "Tuf-Plate Hole" for: PT Aug 27
- Printers, High-Speed Terminal, Using the Burroughs Electrostatic Technique: CS Jun 125
- Private Television Microwave System: CS Dec 278
- Probability Density:
  - of Filter Output for Random Telegraphic Signal Input: CT May 228; IT May 228
  - Function, Quasi-Peak Detector to Measure of: I Mar 19
  - of RC Filter Output for Binary Random Input: IT Dec 174
- Probability Distribution of Noise Due to Fading on FM Microwave Systems: CS Sep 161
- Processing Data in Bits and Pieces: EC Jun 118
- Product Selection: EM Sep 68
- Production Costs, Minimizing, Through Modular Automatic Test Equipment: IE Apr 29; PT Sep 19
- Production, Mechanized, of Equipment of All Lot Sizes: PT Aug 42
- Professional Operations, Management Control of: EM Sep 81
- Profitability Criterion for Measurement and Decision-Making: EM Sep 65
- Projector, Running Your Own: EWS Jan 33
- Propagating Structures, Periodic Coupling of: EC Jul 325
- Propagating Structures with Variable Parameter Elements, Properties of: EC Sep 307
- Propagation:
  - Along Yagi Structure, Phase Velocity of: AP Jul 234
  - through Anisotropic Layers: P Dec S296

  Beyond-the-Horizon, Sweep-Frequency Studies in: AP Oct 428
  Beyond the Radio Horizon, Tropospheric, Diffraction Theory of: AP Jul 261, 268
  Constants of Circular Cylindrical Waveguides Containing Ferrites: MTT Jul 337
  Constants in Waveguide Partially Filled with Dielectric: MTT Apr 294
  in a Dielectric-Loaded Waveguide: MTT Apr 202
  Ground Wave Pulse: AP Jan 1
  of HF and VHF in the Arctic Region: CS Jun 121
  through Hypersonically Produced Plasma: AP Jul 240
  in Ionized Gases: AP Dec S340
  Scatter Experiment Using Six Paraboloids: AP Oct 419
  Scattering of Waves, Modified WKB Methods for: AP Dec S320
  of Space-Charge Waves in Diodes and Drift Spaces: ED Apr 225
Propulsion:
  and Astronautics: MIL Apr 58
  Controlled: AC Dec 30
  Fusion, for Space: MIL Apr 52
  Ionic, Problems in: MIL Apr 27
  Plasma, for Space Flight: MIL Apr 34
  Plasma Possibilities: MIL Apr 42
"Proselyting"—Good Business?: EM Mar 37
Publications as Tools of the Electronics Industry: EWS Jun 49
Pulse Amplifiers, Transistorized Linear: NS Jun 57
Pulse Circuits, Transistor, for 160 MC Clock Rates: EC Dec 432
Pulse Code Modulation, Application to Aircraft Flight Testing: SET Sep 148
Pulse Code Modulation Telemetry, Standards for: SET Dec 194
Pulse Controlled Integration in Automatic Flight Control Systems: AC Dec 133
Pulse-Modulated Time Series, Optimal Filtering of Periodic: IT Jun 67
Pulse Modulators, Semiconductor Diode Amplifiers and: ED Jul 341
Pulse Phase-Change Signaling in the Presence of Ionospheric Multipath Distortion: CS Jun 102
Pulse Return from a Sphere: AP Dec S43
Pulses, Diffraction and Refraction of: AP Dec S78
Pulse-Time Positioning for Safety Control of High-Speed Tester: IE Jan 25
Pulse Transformers, Nanosecond: NS Mar 26
Pump-Oxygenator, Gibbon-Mayo: ME Jun 92
Punched-Card-Controlled Component-Part Insertion Machine: PT Aug 39

Q

Quality Control, Sonic Tester for Casting: IE Jan 46
Quality Control Through Mechanized Assembly and Test, Increased Reliability and Better: PT Jun 22
Quantized Systems, Phase Plane Analysis in: AC Nov 43
Quarter-Wave Compensation of Resonant Discontinuities: MTT Apr 296
Quasi-Peak Detectors with Specified Time Constants, Design of: RFI May 18

R

Radars:
  Auroral Echoes 400-MC: AP Apr 127
  Beacons for Missiles: MIL Oct 175
  Dectection, First Probability of: IT Mar 9
  Echo-Measuring, Time Gate for: I Dec 79
  Filter for Suppressing Spurious Transmission from: MTT Jul 369
  Fog and Rain, Degradation by: ANE Mar 26
  Measurements, Indeterminacy of: ANE Dec 219
  Rain Cancellation: AP Apr 199
  Simulated Airborne, Synthetic Representation of Terrain Features on: MIL Jul 75
  Simulator, Land-Mass: MIL Jul 105
  Simulator, Tracking Thirty-Two Aircraft: MIL Jul 114
  Weather, Oscilloscope Display for: ANE Mar 31
Radiations:
  Between Parallel Plates, Cylindrical Antennas: AP Apr 162
  Effects in Silicon Solar Cells: NS Jun 49
  and Guided Waves: AP Dec S191
  Microwave, from Ferrimagnetically Coupled Electrons: MTT Jan 6
  Pattern, Current Distribution over a Cone Surface for a Prescribed, Correction to: AP Jan 104
  from Ring Sources in Presence of Cone: AP Apr 168
  from Slot Arrays on Cones: AP Jul 213
  Space, Detection and Evaluation of: MIL Oct 160
  from Thin Wire Loop Antenna Embedded in a Spherical Medium: AP Oct 345
  Tolerant Electronic Equipment: NS Dec 12
Radiators, Isotropic, Directivity of Broadside Array of: AP Apr 197
Radio Compass Testing with Small Shielded Enclosures: ANE Mar 4
Radio Flutter in Future Communications: VC Sep 27
Radio-Line, A 215-Mile 2720-MC: AP Apr 117
Radio Link Communication Reliability: CS May 47
Radio Links, Correlation Function and Power Spectra of: AP Apr 137
Radio Relay Systems, Operation of Closed-Spaced Antennas in: VC Sep 11
Radio-Telephone Design, Mobile, Compactness in: VC Sep 64
Radio Telescopes, Synthesis of by Use of Radio Interferometers: AP Dec S120
Radioisotope Detectors, External, Measurement of Branched Flow by: ME Dec 287
Radioisotope Monitor, A Stack Effluent: NS Dec 20
Railroads, Vehicular Communications for: VC Apr 62
Random, Pseudo, Sequences, Two Properties of: IT Mar 32
Random Sampling: Effect on Spectral Density: AC Dec 198
Range and Instrumentation Safety System for Vandenberg Air Force Base: SET Mar 14
Range Measurements, Simultaneous, Position Information Using: ANE Sep 111
Rare-Earth Metals, Magnetism and: CP Jun 93
Rating and Application Considerations for Silicon Diodes: CP Dec 269
Rating System Produce, Making a Multiplant Supplier: RQC Jun 7
Reactive Effects in Forward Biased Junctions: ED Jul 330
Reactance Surface, Sinusoidally-Modulated Guided Waves on: AP Dec S201
Reaction Wheel Attitude Control for Space Vehicles: AC Dec 139
Reactor Instrumentation, Servologarithmic Amplifier for: NS Mar 11
Reactor, Transistorized, Instrumentation and Protective Circuits: NS Jun 42
Reader's Eyes, Use Your: EWS Jan 6
Readout, Nondestructive, of Metallic Tape Computer Cores: EC Dec 470
Read-Out Technique, Glow Counting Tube: EC Sep 317
Real Function, Positive, Generalizations of the Concept of: CT Dec 374
Realizability of Matched N-Port Lossless Junctions: CT Dec 388
Rearview Mirror, Automatic: IE Jul 43
Receivers:
  Automobile, Employing Drift Transistors: BTR Dec 38
  Automobile, Transistor, Front End Design: BTR Dec 31
  FM, Drift Transistors in: BTR Jan 13
  FM Multiplex Stereo: BTR Dec 70
  Synchronous Communications, for the Military UHF Band: CS Jun 129
  Television, Color Decoder Design: BTR Jan 27
  TV Color, Simplification of Controls on: BTR May 54
  Television, Deflection Oscillators for: BTR May 33
  Television, Delta Sound System for: AU Jan–Feb 16
  Television, Modification for 50 Cycles: BTR May 50
  TV, Transistor IF Amplifiers for: BTR May 25
  Transistorized Broadcast, Improvements in: BTR Dec 46
  VHF Pocket: VC Sep 20
Reception, Optimal Properties in Statistical Theory of: IT Sep 138
Recognition, Machine, of Hand-Sent Morse Code: IT Mar 17
Recognition, Minimum-Scan Pattern: IT Jun 52
Recognition Systems, Optimum Character: EC Jun 230
Recorder, Automatic Digital, for Timing Sequential Events: ME Sep 157
Recorder Operation, Economics of Video Tape: BC Feb 25
Recorder, Very High Speed Facsimile: CS Dec 257
Recording:
  Bubble Flowmeter, Automatic: ME Dec 274
  Cardiac Output, Magnetic Flowmeter for: ME Dec 232
  Data, Figure of Merit for: EC Mar 48
  Digital Data for Analysis of Primate Behavior: ME Sep 121
  Electrocardiographic, Analysis, and Diagnosis: ME Sep 112
  Electrocardiographic Data for Analysis by Computer: ME Sep 167
  Magnetic, for Industrial Control: IE Dec 53
  Magnetic, New Techniques for Data Processing: IE Dec 47
  Magnetic Tape, with Longitudinal or Transverse Oxide Orientation: AU May–Jun 76
  Magnetic Tape, Null Alignment in: AU Sep–Oct 116
  Multiple-Channel Tape, for Biomedical Purposes: ME Sep 171
  Optical or Pen, Integrating Drop-Flowmeter for: ME Dec 234
  on Saturation-Type: EC Jun 159
Recruiting: EM Mar 14
Rectangular Wave Functions: I Dec 112
Rectangular Wave Functions and the Concept of Sign Correlation: I Mar 36
Rectifier, Frequency characteristics of Semiconductor: ED Apr 125
Rectifier, Germanium Microwave Crystal: ED Jan 83
Recurrent Events in a Bernoulli Sequence: IT Dec 179
Redundancy, Comment on Pattern: IT Mar 34
Redundancy, Two-Dimensional Predictive, in Television Display: CS May 57
Redundant Machines, Increasing Reliability by: EC Jun 125
Re-Entry, Hypersonic, Optical Communication During: CS Jun 68
Reflection:
  Coefficient Chart to Include Active Networks, Extension of: MTT Apr 298
  Coefficient Measurements, Microwave, VSWR Responses for: MTT Jul 346
  Coefficient Zero Locations: CT Mar 81
  on Incidence Angle, Dependence of: MTT Oct 423
Reflectometer Techniques, Microwave: MTT Jul 351
Reflectors:
  Corner Antennas, Gains of: AP Jul 281
  for a Fabry-Perot Interferometer: MTT Apr 221
  Inverse Scattering Problem: AP Apr 146
  Spherical, as Wide-Angle Scanning Antennas: AP Jul 223
Refraction and Diffraction of Pulses: AP Dec S78
Refraction, Atmospheric, Comparison of Computed With Observed: AP Jul 258
Regal Approach and Landing System: ANE Jun 115
Regulation, Effect of Power Source, on Control System Amplifier Response: AC Dec 59
Rejection Filter, High Power Microwave: MTT Oct 461
Relay, The Trinistor Switch Solid-State Power: NS Jun 69
Relativistic Consideration of Doppler Shift: ANE Mar 37
Reliability:
  Analysis of Recoverable Missiles: RQC Jun 34
  Component, Long-Term: CP Jun 62
  Confidence Interval on Predicted System: RQC Jun 64
  Design Review, Increased System Worth Through: RQC Jun 70
  Mechanized Assembly and Test for Increasing: PT Jun 22

  Military Research Applied to Industrial Electronics: IE Dec 34
  Parts Specifications Management for: CP Sep 128
  of a Physical System: CT May 138; IT May 138
  Poincaré Metric, of Switching Components: IT Sep 137
  Program, Heart of: RQC Jun 16
  Radio Link Communication: CS May 47
  Redundant Machines: EC Jun 125
  Sample Size and Test-to-Failure: RQC Jun 24
  Space Systems Using Ballistic Missile Boosters: MIL Oct 173
  Stochastic Combinational Relay Switching Circuits: CT Mar 131
  Systems Engineering: MIL Jan 8
Reliable Design and Development Techniques: PT Sep 30
Remote Control, Television Wireless: BTR Jan 76
Renal Function, Supplementation by Artificial Means: ME Mar 11
Repeaters, Components for Submarine Telephone Cable: CP Mar 34
Research:
  and Development Cost Estimation: EM Mar 8
  and Development, Management of: EM Sep 75
  Industry-University Cooperation in: EM Mar 12
  Laboratory, Merit Rating and Productivity in a: EM Mar 31
  Laboratories, Administering Information Input and Output in: EM Jun 55
Residue Number System, The: EC Jun 140
Resistors, Fixed Recent Developments in: CP Jun 109
Resistors, Noise in Metal Film and Carbon Film: CP Jun 58
Resistors, Nonlinear, Generation of Squares with: CT Dec 334
Resonance and Supergain Effects in Loaded Biconical Antennas: AP Dec S414
Resonant Cavities, Design of Open-Ended: MTT Jul 389
Resonant Discontinuities, Quarter-Wave Compensation of: MTT Apr 296
Resonators, X-Band Cavity End Plate Modification of: MTT Jul 388
Response of a Linear System to an FM Signal: CT Dec 387
Respiration, Artificial: ME Mar 29
Respiration, Artificial, CO_2 Control of: ME Mar 30
Respiration, Physiological Considerations of: ME Mar 24
Rhombic Antenna Arrays, Design of: AP Jan 39
Rhombic Antenna, Gain and Current Attenuation of: AP Apr 188
Riblet's Theorem, Comment on: MTT Oct 477
Rocket for Manned Lunar Exploration: SET Dec 155
Rockets, Electron Densities of the Ionosphere Utilizing: AP Oct 414
Root-Locus Method for the Analysis of Nonlinear Servomechanisms: AC Dec 38
Routh's Algorithm to Network-Theory Problems, Applications of: CT Jun 144
Rubber, Silicone, Use in Medicine: ME Mar 51
Rubidium Gas Cell Frequency Standard: MIL Oct 178
Russian Test Equipment for Audio, Radio, and Microwave Measurements: I Dec 67
Russian Visit to U.S. Computers: EC Dec 489

Secondary Emission, Effects of Initial Electron Velocities and Space Charge in: ED Oct 397
Secondary School Cooperation, IRE and: E Jun 67
Selective, Digital, Signaling System for Mobile Radio: VC Apr 74
Selective Signaling in the Bell System: VC Apr 67
Selector, Transistorized, Device for Mobile Telephone: VC Apr 71
Semiautomatic Circuit Component Tester: PT Sep 12
Semiconductors:
  Devices, Lumped Model of Noise in: ED Apr 133
  Devices, Thermally Induced Cracking: ED Jul 299
  High-Speed Microwave Switching of: MTT Apr 272
  Nesistor, Negative Resistance Device: ED Jul 278
Seminar, Working with Electrical Engineers in: EWS Jun 46
Senior-Year Semiconductor and Electron Device Course: E Mar 6
Sensitivity Theorem: CT Mar 131
Sequences, Two Properties of Pseudo-Random: IT Mar 32
Sequential Circuits:
  Asynchronous Switching, Hazards and Delays in: CT Mar 12
  Autonomous, Matrices in Theory of: CT Dec 392
  Autonomous Linear: CT Mar 45
  Coding Networks, Linear Multivalued: CT Mar 69
  Equivalent Circuits: CT Mar 30
  Linear Modular: CT Mar 61
  Linear Modular, Periodicity of States in: IT Sep 136
  Modular, Application to Error-Correcting p-nary Codes: IT Sep 114
  The Number of Internal Variable Assignments for: EC Dec 439
  Transducers: CT Mar 4
  Transducers, Memory Aspects of: CT Mar 26
Sequential Detection, Experimental Results in: IT Jun 41
Sequential Events, Timing, Automatic Digital Recorder for: ME Sep 157
Sequential Machines, Minimal: EC Sep 339
Sequential Machines, Synthesis Technique for Minimal State: EC Mar 13
Sequential Machines, Transition Matrices of: CT Mar 5
Sequential Switching Functions, Minimizing the Number of States in: EC Sep 356
Serrodyne, Ferrite, for Frequency Translation: MTT Jan 32
Servo Design, Hot Gas: AC Dec 97
Servologarithmic Amplifier for Reactor Instrumentation: NS Mar 11
Servomechanisms, Adaptive: ME Sep 134
Servomechanisms, Nonlinear, Root-Locus Method for the Analysis of: AC Dec 38
Servos:
  Comparison of Stabilization Techniques for: AC May 7
  Instrument, for General Purpose Computation: IE Apr 1
  Parameter Tracking, for Adaptive Control Systems: AC Nov 100
  Positioning, for Automatic Machine Tool Operation: IE Jan 31
  Position and Velocity, for Multiplying and Function Generation: EC Sep 391
  Predictor-Relay, with Random Inputs: AC Dec 232
Shift Register, Electro-Optical: EC Jun 113
Shot Noise, Second-Order Distribution of Integrated: IT Jun 75
Sideband Signals in the Presence of Noise, Detection of Asymmetric: BTR Jan 46
Signaling, Pulse Phase-Change, in the Presence of Ionospheric Multipath Distortion: CS Jun 102
Signal Flow Graphs, Equivalent Ladder Networks by Use of: CT Mar 75
Signal-Flow Graphs, Node Duplication—Transformation of: CT Jun 233
Signal Generator Attenuator Calibration, Voltmeter for: I Mar 22
Signal-to-Noise Ratios in Smooth Limiters: IT Jun 79
Signals, The Representation of: CT May 197; IT May 197
Signal-Seeking Receivers and Automatic Sweep Circuits, Voltage Variable Semiconductor Capacitor in: BTR Dec 16
Signal Waveform, Estimation of: IT Jun 86
Silicone Rubber, Use in Medicine: ME Mar 51
Silicon, Making Crack-Free Alloyed Junctions in: ED Jul 358
Silicon Solar Cells, Radiation Effects in: NS Jun 49
Simulated Airborne Radar Display, Synthetic Representation of Terrain Features on: MIL Jul 75
Simulating, Human Disorientation Device, of Angularly-Accelerated Motion: MIL Jul 99
Simulation:
  of Air Duel Environment: EC Mar 55
  Analog-Digital Computer for: EC Jun 186
  of Earth's Topography for Research and Engineering: MIL Jul 87
  Ground, of Space Flight Environment: SET Jun 57
  Non-Real-Time, of Sage Tracking and BOMARC Guidance: EC Mar 36
  Operational Analog, of the Vibration of a Structure: EC Sep 381
Simulator, Integrated Space-Flight: MIL Jul 92
Simulator, Land-Mass Radar: MIL Jul 105
Simulator, Thirty-Two Aircraft Radar Track: MIL Jul 114
Single-Sideband Carrier Systems for High-Speed Data Transmission, Synchronization of: CS Jun 110
Single-Sideband Modulator, Ferrite Half-Wave Plate for: MTT Apr 295

Single Sideband Power Amplifiers, Analysis of: CS May 53
Slot Arrays on Cones, Radiation from: AP Jul 213
Slots, Closely-Spaced Transverse, in Rectangular Waveguide: AP Oct 335
Slotted Dieletric Interfaces, Properties of: AP Jan 62
Slow Wave Structures, Waveguide-Coupled: ED Jan 9
Smoothing, Nonstationary, and Prediction Using Network Theory Concepts: CT May 1; IT May 1
Sodium Vapor, Microwave Frequency Standard Employing Optically Pumped: MTT Jan 95
Solar Cells, Radiation Effects in Silicon: NS Jun 49
Solid-State Automatic Flight Control Systems: AC Dec 114
Solid-State Maser, UHF: MTT Jan 92
Solid-State Microwave Amplifiers: MTT Jan 83
Sonic Tester for Casting Quality Control: IE Jan 46
Sound:
  Compatible Stereophonic: BC Nov 16
  Compatible Stereophonic: AU Nov–Dec 169
  Delta, for Television Receivers: AU Jan–Feb 16
  New Dimensions in: BC Nov 19
Space:
  Capsules, Telemetered Parameters of Primates and Humans from: SET Sep 99
  Charge Layer Width in Diffused Junctions: ED Oct 405
  Charge in Secondary Emission, Effects of Initial Electron Velocities and: ED Oct 397
  Charge Waves in Diodes and Drift Spaces, Propagation of: ED Apr 225
  Communication, Design Considerations for: CS Dec 232
  Communications, Doppler Phenomena in: CS May 25
  Exploration, Communication Techniques for: SET Sep 95
  Flight Environment, Ground Simulation of: SET Jun 57
  Flight, Plasma Propulsion Devices for: MIL Apr 34
  Flight Simulator, Integrated: MIL Jul 92
  To-Ground Transmissions Beyond the Line-of-Sight: SET Dec 179
  Navigation, Gravitation Field and Application to: SET Mar 47
  Propulsion, Fusion for: MIL Apr 52
  Radiations, Detection and Evaluation of: MIL Oct 160
  Systems, Reliability, Using Ballistic Missile Boosters: MIL Oct 173
  Vehicle Communication, Optimum Frequencies for: CS Sep 167
  Vehicles, Attitude Control of: AC Dec 34
  Vehicles, Direct Energy Conversion Devices for: MIL Apr 46
  Vehicles, Tracking of: MIL Oct 162
  Vehicles, Reaction Wheel Attitude Control of: AC Dec 139
Speak, Can They See What You Say When You: EWS Jan 24
Specification Limits, Evaluation of Ball Bearings To Establish: RQC Jun 77
Specifications Management for Reliability: CP Sep 128
Spectral Characterization of Control System Nonlinearities: AC Dec 199
Spectral Density, Effect on, Random Sampling: AC Dec 198
Spectral Properties of Weighted Random Noise: IT Sep 123
Spectrograph, Microwave Electron Velocity: ED Jan 64
Spectrum Analyzer, Cross, Analysis of Electroencephalograms by: ME Sep 149
Speech Techniques, Study of Writing and: EWS Jan 12
Speech Transmission, Extremal Coding for: IT Sep 129
Speech Transmission, Narrow Band, Time-Frequency Scanning in: AU Nov–Dec 148
Sperm Cells, Effects of Electric Fields on Movements of: ME Sep 174
Spherical Reflectors as Wide-Angle Scanning Antennas: AP Jul 223
Spiral Equiangular Antenna: AP Dec S117
Spurious Mode Generation in Nonuniform Waveguide: MTT Jul 379
Spurious Transmission from *S*-Band Radar, Waveguide Filter for Suppressing, Correction to: MTT Jul 369
Stability of Circuits With Randomly Time-Varying Parameters: CT May 260; IT May 260
Stability Criteria in Rectangular Coordinates: AC May 69
Stability, Mean Square, of Random Linear Systems: CT May 248; IT May 248
Stabilization, Signal, of Self-Oscillating Systems: AC Dec 37
Standards for Pulse Code Modulation Telemetry: SET Dec 194
Statistical Filter Theory for Time-Varying Systems: AC Nov 74
Statistical Theory of Reception, Optimal Properties in: IT Sep 138
Steady-State Analysis of Circuits Containing a Periodically-Operated Switch: CT Sep 252
Steady-State Transmission through a Network Containing a Single Time-Varying Element: CT Sep 244
Steel Mill Processes, Data-Logging and Programming in: IE Jul 24
Stepped Zone Mirror for Microwaves, Experimental Test of: AP Dec S125
Step Response, Bounded Nondecreasing: CT Mar 129
Stereophonic:
  Broadcast System, Optimized Compatible AM: BC Nov 2
  Frame-Grid Audio Pentode for: AU Jul–Aug 101
  Phonograph Cartridges, Two-Channel Ceramic Transducer for: AU Jul–Aug 96
  Playback, Three Channel, Derived From Two Sound Tracks: AU Nov–Dec 161
  Playback, Three-Channel, Two Tracks Derived from Three Microphones: AU Mar–Apr 34
  Receiver, FM Multiplex: BTR Dec 70
  Sound, Compatible: AU Nov–Dec 169
  Sound System, A Compatible: BC Nov 16
  Wide-Stage: AU Jul–Aug 93
Stream Analysis, New Developments in: IE Dec
Strip-Line Balun, Wide-Band: MTT Jan 128
Strip-Transmission-Line Resonator Directional Filters: MTT Jan 168
Strip Transmission Line and Waveguide Multiplexers: MTT Oct 475
Stub Design, Broad-Band: MTT Oct 478
Stylus, Pyramid: AU Nov–Dec 140
Submarine Telephone Cable Repeaters, Components for: CP Mar 34
Success in Science or Engineering: E Jun 94
Supergain and Resonance Effects in Loaded Biconical Antennas: AP Dec S414
Super-Regeneration and Super-Radiation: ED Jul 288
Surface Waves:

Sample cell used at the IBM Watson Laboratory for studies of the self-diffusion of quantum liquids.

Studying Quantum Liquids to Observe Nuclear Theory

omic nuclei are dense systems composed identical particles which obey Fermi-rac statistics. Using these statistics, entists have computed the theoretical havior of the particles which compose avy nuclei.

Helium^3, a quantum liquid, provides entists with an extremely convenient del of this nuclear matter – a model dily accessible to research. A cryogenic uid, He^3 permits the investigation of antum effects. This makes it possible to npare nuclear behavior with theoretical dictions.

Research in quantum liquids is being done at the IBM Watson Laboratory at Columbia University. Direct spin-echo measurements of diffusion and nuclear relaxation were made on He^3 atoms in the pure liquid, and also in dilute solutions of He^3 in He^4. Measurements were made in the temperature range 0.5°K to 4.2°K, at pressures up to 67 atmospheres.

Experiments on the pure quantum liquid revealed diffusion persisting to the lowest temperatures. However, it was apparent that the diffusion was not thermally activated as in an ordinary liquid, or in a gas. Diffusion persisted for two reasons: (1) because of the zero-point energy of the atoms, and (2), because of the atoms' long wave length as compared with the thickness of the potential barriers which inhibited their motion. The results of the experiments on dilute solutions of He^3 in He^4, in accord with expectations, showed that the He^3 diffusion coefficient increased rapidly with decreasing temperature.

This study will help to increase our understanding of quantum systems, and consequently, help to increase our familiarity with nuclear matter.

DEAD END FOR STRAY POWER...

New rotary shutter for S-Band extends reliable standby protection to RG 48/U waveguide systems.

Microwave Associates' new MA-788 rotary shutter puts up an effective secondary barrier to high level signals . . . forms an important element in the guaranteed crystal protection offered by Microwave's complete duplexing units.

NOW—SIX SHUTTERS AVAILABLE

Six magnetically operated rotary shutters for S, X, Ku and Ka bands are now in our line and are charted below. They form the best-yet supplementary protection against crystal damage when radar system is inoperative. They may also be used as on-off waveguide switches for low power applications. In the closed position they create a dead end short circuit across the waveguide, reflecting essentially all the incident power.

COMPLETE DUPLEXERS OR SEPARATE SHUTTERS

They're available as separate units supplied to fit your system or as components in complete duplexers carrying *guaranteed crystal protection for life . . . at full rated power and elevated temperatures.*

SPECIFICATIONS

Band	Type	Frequency kMc	Isolation (Closed position)	Insertion Loss (Open position)	VSWR (Open position)

OTHER MOTOROLA MESA TRANSISTORS INCLUDE:

2N700	UHF Amplifier in TO-17 package
2N705 2N710	Ultra High-Speed Switches in TO-18 package
2N741	VHF Amplifier in TO-18 package
2N1561 2N1562	160 MC Power Amplifier

The I_{CBO} stability of the 2N695 over 2,500 hours of life-test is a vivid example of the extreme reliability of Motorola Mesa transistors.

The ultra-precise processes used in the volume-production of the Motorola Mesa family, and the basic device design combine to give you the most reliable transistors yet available. Greater device reliability means more dependable circuits . . . continued high-quality performance.

USE

HICKORY BRAND

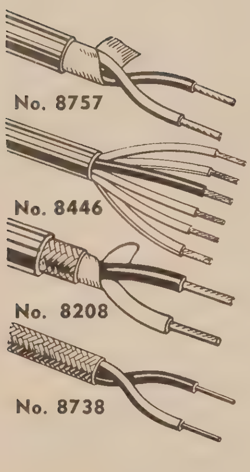
Intercommunicating and Sound System Cables

Manufactured from quality materials, Hickory Brand plastic insulated cables provide long service life and excellent mechanical and electrical characteristics.

Available in shielded and unshielded types for use as inter-connecting cables on electronic equipment, remote control circuits, special microphone circuits, power supply cords and for many other electronic applications.

Quick termination, positive color-coding and small diameters insure maximum economy in all installations.

Representative types:



No. 8757—2 conductors: 20 AWG 7 x 28 Cu. tinned .015" ins. .185" nom. dia.

No. 8446—6 conductors: 4—22 AWG 7 x 30 strand .010" ins.—plus 2 18 AWG 16 x 30 strand .018" ins. .212" nom. dia.

No. 8208—2 conductors: 18 AWG 7 x 27 copper tinned .040" ins. .155" nom. dia.

No. 8738—2 conductors: 22 AWG solid .015" ins. .130" nom. dia.

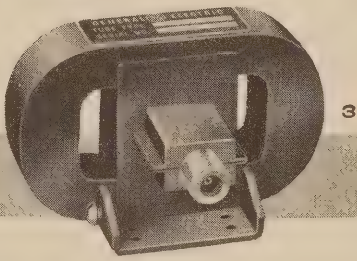
as well as S-Band. General Electric Voltage-oscillate with uniform efficiency, linear tuning.



New L-Band VTM . . . 1000-2300 MCS

3 lbs. . . . Shown 1/4 Size

Features which make the new Z-5405 particularly valuable in equipments like sophisticated radar:

Linear Tuning. Permits designing simpler circuitry to use information generated.

High Efficiency. Eliminates need for forced air-cooling. Also reduces battery load, therefore lengthens battery life.

Uniform Power Spectrum. Assures driving traveling wave tubes at optimum conditions.

Smallest in Size, Lightest in Weight, Higher Power Output. Aids in design of compact, light-weight equipments.

CRYSTAL FILTERS

Within three years Hermes Electronics Co. has become the nation's leading producer of frequency selective devices utilizing piezoelectric crystal resonators. The growing demand for crystal filters and related devices has created a number of career opportunities for: Circuit Design Engineers, Crystal Physicists, and Network Theory Specialists.

Hermes Electronics Co. is a unique organization where responsibility and initiative are encouraged. Here you will also find the stimulation and environment of a young and growing company. Your association will be with staff members who are in the vanguard of many of today's rapidly expanding technical frontiers.

Salaries and other benefits are comparable to those of major research and development organizations. The company's location in Cambridge, Mass. affords unequaled cultural, living, and recreation facilities.

Liberal educational benefits are allowed for graduate study at leading universities in this area.

Interested scientists and engineers are invited to address inquiries to: Mr. E. E. Landefeld, Personnel Director.

Hermes
Electronics Co.
75 CAMBRIDGE PARKWAY
CAMBRIDGE 42, MASSACHUSETTS

Positions Open

The following positions of interest to IRE members have been reported as open. Apply in writing, addressing reply to company mentioned or to Box No. ....

The Institute reserves the right to refuse any announcement without giving a reason for the refusal.

Proceedings of the IRE
1 East 79th St., New York 21, N.Y.

ELECTRONIC ENGINEER

Young Electronic Engineer, experienced in circuit design, to work as assistant to one of the outstanding engineers in the country in the design and development of precision analog equipment. This is once-in-a-career opportunity for the right individual to learn from one who has, over the past 15 years, established a proven record of accomplishment in the analog field. Apply Milgo Electronic Corp., 7620 N.W. 36th Ave., Miami 47, Florida.

STAFF OPENINGS—ELECTRICAL ENGINEERING DEPT.

Staff openings for September 1960 in Electrical Engineering Dept. Mostly undergraduate instruction. Attractive salary, living conditions. Recreation center of the West. Correspondence invited. I. J. Sandorf, Chairman, Dept. of E.E., University of Nevada, Reno, Nevada.

PROFESSOR

The University of Alaska has an opening for an Assistant Professor of Electrical Engineering—to teach and do research on the ionosphere, the aurora, or on problems in communications or power in the North. Industrial experience or advanced degree required. Write Airmail to Dept. of E.E., University of Alaska, Box 497, College, Alaska.

RESEARCH ENGINEER

Engineering or Physics degree. 5-10 years experience in inertial guidance systems and/or components. Aid in developing concepts of advanced guidance systems and in promulgating written and verbal communications on the subject to other groups in allied fields. Send resume to G. A. Nesbet, Litton Industries, Beverly Hills, Calif.

RESEARCH SCIENTIST

Physics degree, advanced preferable. Experienced in thermodynamics, cyrogenics, vacuum technology, optics. Aid in developing space stimulation techniques. Send resume to G. A. Nesbet, Litton Industries, Beverly Hills, Calif.

ENGINEERING EDITOR

Young engineer with an interest in technical publications work has an excellent opportunity for a permanent position on the IRE headquarters staff as assistant to the Managing Editor. Send resume to E. K. Gannett, Managing Editor, Institute of Radio Engineers, 1 East 79 Street, New York 21, N. Y.

TEACHING POSITION

Expanding, recently organized dept. with a modern science-oriented curriculum, seeks a well-qualified person who is interested primarily in teaching. Advanced degree required. This is an unusually attractive position for the right individual. 12 month salary assured, if desired for approximately 10½ months service. Possible to have every other summer off while earning full salary. Salary range is approximately

(Continued on page 118A)

COMPUTER SYSTEMS SUPERVISOR

We are seeking an engineer with a record of outstanding achievement in research and development to direct the activities of our Computer Systems Section. As supervisor of this important activity, you will have the opportunity to develop research programs of greatest appeal to you and your staff in the following areas:

- Analysis of Components and Systems
- Advanced Development
  - Digital System Organization
  - Logic
  - Storage
  - Input/Output
- Self-Organizing Systems

As a Foundation staff member you will be joining a mature, independent research organization with a staff of over 600 engineers and scientists contributing to a wide variety of military and industrial research programs.

You will receive a competitive salary plus liberal insurance and retirement benefits in addition to four weeks vacation after one full calendar year of service. Our location in a major midwestern city offers excellent cultural and recreational opportunities.

If this is the unusual professional opportunity you have been looking for, reply in confidence to:

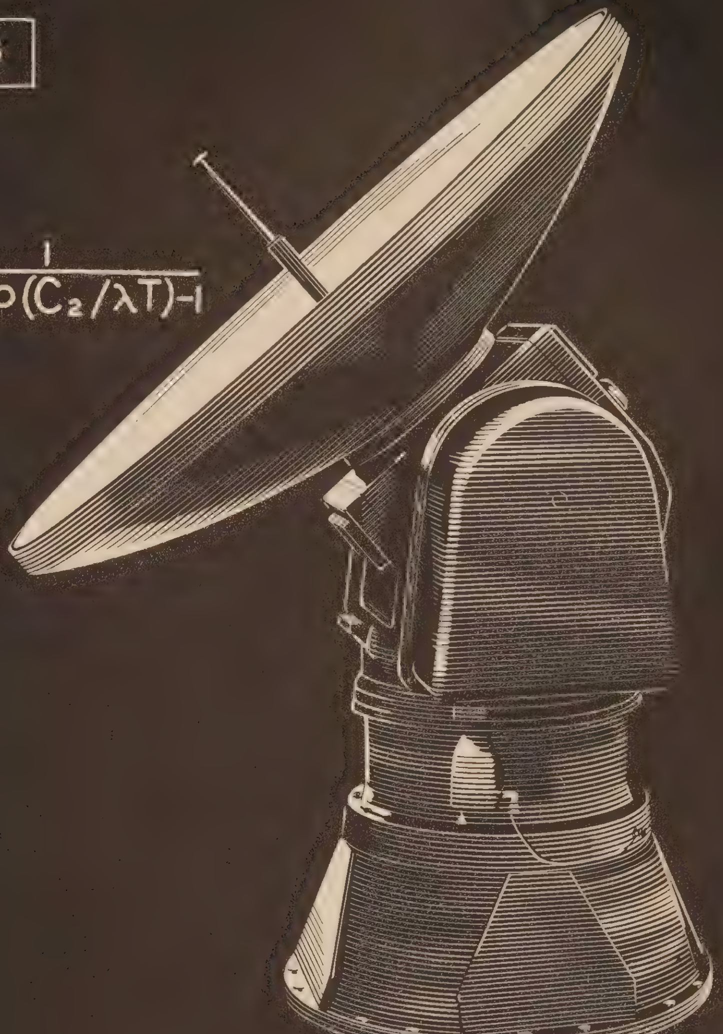
A. J. Paneral
Armour Research Foundation
of Illinois Institute of Technology
10 West 35th Street
Chicago 16, Illinois

RESEARCH AT COLLINS

$$p(\lambda)d\lambda = \frac{C_1}{\lambda^5}\,\frac{1}{\exp(C_2/\lambda T)-1}$$

$$C_1 = 8\pi hc$$

$$C_2 = \frac{hc}{k}$$



THE UNUSUAL SHAPE OF PROGRESS

The principles of spectral energy distribution of the radiation from a black body, announced by Max Planck in 1900, were of intense interest to the theoretical physicists of the day. Since then, these principles have paved the way for major advances in marine navigation and radio astronomy. For example, Collins new Radio Sextant pictured here is capable of continuously tracking the sun or the moon under any weather conditions, furnishing both the ship's location and heading with high precision.

Max Planck's work was done in an atmosphere of unrestricted scientific freedom. Such an atmosphere is provided in Collins Radio Company Research laboratories for physicists, mathematicians and engineers engaged in basic research. These are men capable of looking beyond man's present limitations, with the ability and ambition to analyze man's progress and envision his future environment. To further implement the advancement of scientific knowledge at Collins, with the resultant development of new technologies, unique professional opportunities are now being offered in the fields of radio astronomy, circuits, advanced systems, antennas and propagation, mechanical sciences and mathematics. Your inquiry is invited.

COLLINS RADIO COMPANY • CEDAR RAPIDS, IOWA • DALLAS, TEXAS • BURBANK, CALIFORNIA

ENGINEERS

NOW—CHOOSE YOUR ASSIGNMENT AND LOCATION THROUGH OUR NATION-WIDE PLACEMENT SERVICE

SALARIES $7,500 TO $18,000

We can offer you a large selection of diversified positions with America's foremost electronic organizations. Some positions for non-citizens.

The following are just a few of a large number of desirable opportunities.

SR. ENGR.—DIGITAL COMPUTERS— Exp. required in systems, logical design, packaging, system integration or pulse circuitry. To $15,000

FLIGHT TEST EVALUATION—Sr. Opp. in Ground & Flight Test on data links, precision transducers, telemetering equipment, power supplies, circuit monitors and impedance matching units. To $15,000

RF ANTENNA—Proj. Engr. $15,000

INFRA RED—Proj. Engr. $15,000

CIRCUIT DESIGNERS — 2-5 years Transistor experience. $11,000

ADVANCED SYSTEM DEVELOPMENT —Supervisory position in digital computer, fire control or missile guidance development. To $17,000

PHYSICIST Phd.—Nuclear experience pertaining to radiation from propulsion units—unusual opportunity. To $18,000

PROJECT LEADER—Antenna Pedestals. $13,000

SR. ENGINEER—DEVELOP Airborne & spaceborne communications systems. $15,000

Just tell us what you would like to do and where you would like to locate, and we will handle everything for you without cost or obligation.

☐ Dig. Computers
☐ Antenna
☐ Servo-Mechanisms
☐ Navigation
☐ Counter Measures
☐ Telemetering
☐ Nucleonics
☐ Ind'l. Instruments
☐ Components
☐ Circuit Design

WHAT SATISFIED ENGINEERS SAY:

Dear Mr. Brisk:
This is to advise you I have accepted employment with ———— Company as a project leader at $15,000.
Your service has been a real help to me, for I am sure I could not have found this unusual opening by myself.
Thank you.
H.M.P.

Dear Mr. Brisk:
I have today advised ———— Company that I would be pleased to accept their offer. I start August 1st as a senior engineer at $13,000.
The opportunity is one of the most outstanding I have seen.
J.S.E.

A National Electronic Placement Service Established in 1937.

Positions Open

(Continued from page 116A)

$6,000 to $8,000. Private, medium-sized university in midwest. Send complete resume to Box 2011.

ENGINEER

Electronics Research and Development Lab. needs man with experience in transistor-circuit development. Position carries opportunity to study for advanced degrees in Physics or Engineering. Salary consistent with training and experience. Applicants will be required to have BS. degree or better in Physics or Engineering to qualify. For more details write Research Foundation, Oklahoma State University, Stillwater, Okla., or call R. F. Buck, FRontier 2-6211, Ext. 579, after 5 P.M. or holidays call FRontier 2-8480.

ELECTRICAL ENGINEERS

University appointments Electrical Engineering. Three openings including the Chair in Electrical Engineering in new Faculty of Applied Science with opportunity for advancement and research. Attractive salary schedule. New building under construction. Ph.D. or Master's degree desirable. Apply to F. A. DeMarco, Principal, Essex College, Windsor, Ontario.

TEACHING POSITION

Expansion of graduate work in E.E. at Syracuse University has created several opening at the Assistant and Associate Professorial ranks. Except in very unusual circumstances, applicants should have a Doctorate in E.E. or a closely allied field. Opportunities exist for combination of teaching and research during the academic year, and for summer employment on research. Teaching is primarily at the graduate level. Salary depends on experience, but in most cases the yearly salary (for 11 months work) is reasonably competitive with industry. Write to Dr. W. R. LePage, Chairman, Dept. of E.E., Syracuse University, Syracuse 10, New York.

ASSOCIATE OR ASSISTANT PROFESSOR

Expert in field of semiconductors. Ph.D. is minimum requirement, applicant must have some teaching experience. Academic rank and salary dependent on demonstrated ability and over-all experience. The man in this position will divide his time between teaching and research. Appointment begins Sept. 1960. Write, including resume to W. R. Beam, Head, E.E. Dept., Rensselaer Polytechnic Institute, Troy, N. Y.

EDITOR

Scientific book publisher needs radio engineer to plan and develop new books. Publishing experience desirable. Write in detail. State salary. Box 2012.

ENGINEERS

Major firm seeking (1) Section leader, Electromechanical design, (2) Section leader, testing and reliability, knowledge of Military acceptance testing, (3) Manufacturing engineers, knowledge of standards, process and tool engineering for electromechanical display equipment. Top future positions. Benefit programs. Salaries $8,000–$15,000. Contact Mr. W. Hart, Witty-Polon Management Consultants, 176 East 75 St., New York 21, N. Y. Telephone: Lehigh 5-4222.

INSTRUCTOR AND ASSISTANT PROFESSOR

For those interested in teaching fundamental electrical & electronic subjects. Opening for fall semester beginning Sept. 1960. Salary depends

LISTEN!...

To the Westinghouse-Baltimore Story

Before you make your career decision, you should hear the story that is now unfolding at the Baltimore Divisions of Westinghouse. Get the facts on the exciting programs now under way . . . including advanced development work on new weapons systems with revolutionary data processing, antenna systems, and system synchronization. If you are beginning or continuing your career as an electrical or mechanical engineer, we would welcome the opportunity to give you the facts about career opportunities in the following fields:

MICROWAVE SYSTEMS
SYSTEM SYNCHRONIZATION
SYSTEMS RELIABILITY PREDICTION
MOLECULAR ELECTRONICS
ADVANCED DATA DISPLAYS
LIAISON AND FIELD ENGINEERING
MECHANICAL DESIGN & PACKAGING
DIGITAL COMPUTER DESIGN
ADVANCED ANTENNA SYSTEMS
ADVANCED SYSTEMS AUTOMATED TEST
TRANSMITTER AND RECEIVER SYSTEM DEVELOPMENT
TRANSFORMER DESIGN

Send resume to: Mr. A. M. Johnston, Dept. 279

on qualifications. New building and equipment. Opportunity for advancement and further study. 9 month academic year. Part time evening session work available. Health Insurance and Pension Plan. Send complete resume to Prof. I. L. Kosow, Dept. Head. Electrical Technology, Staten Island Community College, 50 Bay St., Staten Island 1, N. Y.

ELECTRICAL ENGINEERING PROFESSORS

Fast growing Engineering School on west coast needs 3 electronic-electrical engineers able to teach circuits and electronics, with a specialty in communications, industrial electronics or computers. MS. degree plus industrial experience is the minimum requirement; a Ph.D. is desirable. Salary and rank will depend on experience. The dept. has just moved into a new building and needs aggressive men who wish to develop curricula and labs. Apply L. Cromwell, Head, E.E. Dept., Los Angeles State College, 5151 State College Dr., Los Angeles 32, Calif.

PROFESSOR

Assistant and/or Associate Professor of E. E. with interest and experience in one of the following areas: electromagnetic theory, information theory, digital computer logic and numerical methods, solid state. Ph.D. required, Combination of reasearch, graduate and undergraduate teaching. Address inquiries to Dr. C. Polk, Head Dept. of E.E., University of Rhode Island, Kingston, Rhode Island.

PROJECT ENGINEER

Project Engineer to supervise complete projects in design and development of automatically sequencing, self checking test equipment used to evaluate complex airborne guidance systems and components, as well as industrial process instrumentation. E.E. plus 5–7 years experience. Kearfott Div.—General Precision, Inc. Att: P. Kull, 1500 Main Ave., Clifton, New Jersey.

SENIOR ELECTRICAL ENGINEER

E.E. degree and 8-10 years experience including experience in electronics. Interesting work in conjunction with a nuclear physics research program. Benefits include a reduced tuition rate for the employee and free tuition for children of employees with 5 or more years of service. If interested, send complete resume, including salary expectations to J. R. Whitley, Employment Supervisor, University of Rochester, 260 Crittenden Blvd., Rochester 20, N.Y.

MEDICAL ELECTRONICS

Biophysical Electronics, Inc. devotes its efforts to the design and manufacture of instruments assisting the physician, psychologist, and research scientist to meet the challenge of preserving and extending life. Positions are open for: Senior Transistor Circuit Designer, Sales and Office Manager and experienced Electronic Technician. Submit resume, availability and salary requirements in first letter to Biophysical Electronics, Inc., New Hope, Pa.

ELECTRONICS ENGINEER OR PHYSICIST

High qualifications and varied experience, particularly in control, rf or nuclear electronics. Appointment as Assistant Professor at $7,000-$8,900 or as Associate Professor at $9,000-$11,700, or to non-academic position at equivalent salaries. To supervise construction of a spiral-ridge cyclotron to produce 50 Mev protons.

succeed in '60 with T/I

the careers of these S/C engineers are assured at T/I in '60

DEVICE DEVELOPMENT ENGINEER. *Mission:* Probing the unknown to evolve a variety of new advanced semiconductor-component devices.

CIRCUIT DEVELOPMENT ENGINEER. *Mission:* Discovering through experience and educated imagination, new uses for transistors and specialized semiconductor devices by exploring new frontiers in thought.

Device and Circuit Development Engineers we seek, want liberal freedom of thought and action and advanced physical facilities to permit maximum creative productivity. They desire broad and rapid expansion of their professional horizons with solid financial security and recognition matching personal achievements.

Our Device Development Engineer would be equally intrigued with studies in solid-state diffusion and nuclear radiation experimentation on semiconductor materials and devices. Our Circuit Development Engineer would be productively stimulated by participation in transistorization projects ranging from AM, FM and TV receivers to computer system logic.

You qualify as our Device Development Engineer if you hold a degree in Electrical Engineering, Chemistry or Physics and experience in semiconductor or related development areas. An Electrical Engineering degree and knowledge of transistor circuitry are required for Circuit Development Engineers.

START NOW TO SUCCEED IN '60 AT TEXAS INSTRUMENTS

INTERVIEWS will soon be held in your area. If you qualify for either of these positions, please send a resume immediately to C. A. BESIO, DEPT. 105.

ENGINEERS

Join Sanders Associates and combine PLEASANT COUNTRY LIVING with a TOP FLIGHT ENGINEERING CAREER

At Sanders Associates—located in the friendly New England community of Nashua, N.H.—you will find a variety of engineering programs that probe deeply into advanced areas of electronic and electromechanical systems and components for industry and defense.

Here in the fresh clean world of the country, away from the soot, and strain of heavily populated areas, you will discover that Sanders can offer you a wide range of opportunities—at fully competitive salaries.

You will enjoy diversified assignments on technically advanced projects in Radar, ECM, Navigation, ASW systems & devices, Industrial Automation techniques, working with the engineers who originated such products as Panar® radar, Dare target-seeker system, Flexprint® flexible printed circuits, Tri-Plate® microwave products and other Sanders "firsts."

The cost of living is low in Nashua; schools are excellent and attractive homes are available. Downtown Boston is less than an hour away, as are the recreations of mountains, ocean, lakes.

Openings available for:

SYSTEMS ENGINEERS

Through Project Engineer level. Need not be specialists, but must have creative abilities and backgrounds of VHF transmitters and receivers, communications systems in general, data processing techniques, propagation and must be capable of translating this knowledge into complex integrated systems.

RECEIVER DESIGN ENGINEERS

VHF electronically scanned airborne receivers, filters, problems in spurious response reduction and multiplexing.

CIRCUIT DESIGN ENGINEERS

With particular emphasis on transistor application to analog and digital techniques; data handling equipment; audio, video, RF circuitry and switching.

CHIEF MANUFACTURING ENGINEER

10 to 15 years experience in the successful manufacture of complex military electronic systems and instruments

TRANSMITTER & MAGNETIC DESIGN ENGINEERS

GYRO & SERVO DESIGN ENGINEERS

To learn more about opportunity for YOU at Sanders, send a resume to Lloyd Ware, Staff Engineer, Dept. 908

Apply to Dr. B. G. Whitmore, Physics Dept., University of Manitoba, Winnipeg 9, Manitoba, Canada.

ENGINEER

To assist in construction of new cyclotron installation. Permanent position. Experience in building and maintaining scientific apparatus essential. Specific experience with cyclotrons desirable. Salary dependent on qualifications and experience. Apply to Dr. B. G. Whitmore, Physics Dept., University of Manitoba, Winnipeg 9, Manitoba, Canada.

TEACHING-RESEARCH, ELECTRICAL ENGINEERS

Expanding university program provides unusual opportunities for positions combining teaching and research. Rank and salary open. Teaching in all E.E. fields. Research primarily in microwave electronics. Apply: Dean E. C. Easton, Rutgers University, New Brunswick, New Jersey.

TEACHING AND RESEARCH

Attractive opening for Electrical Engineer with Ph.D. to help develop graduate program, supervise graduate research and do some teaching. Encouragement given to private research and consultation. Good salary and faculty ranking will be offered to exceptional individual. Position available Sept. 1960 or sooner. Write, Dean, School of Engineering, Vanderbilt University, Nashville 5, Tenn.

ELECTRONIC ENGINEERS

Positions open to Electronic Engineers teaching lecture and laboratory courses in a rapidly growing 4 year college. A background of servomechanisms, circuit analysis, microwaves, and/or transistors is desired. Applications desired from both academic and industrial personnel. Write, Harold P. Skamser, Dean of Engineering, Calif. State Polytechnic College, Kellog-Voorhis Campus, Pomona, Calif.

TEACHER IN ELECTRICAL ENGINEERING

Teacher in E.E. beginning Sept. 1960. One qualified and interested in teaching fundamental undergraduate courses plus one graduate course. Ph.D. or MS. required with salary and rank dependent on qualifications. City location with many industrial contacts. Apply Dept. of E.E., Saint Louis University, St. Louis 8, Missouri.

STAFF ENGINEER

Research engineering position for creative person to form nucleus of a new section in the Electro-physical Labs. Will propose and evaluate new electronic component, circuit and systems concepts. Minimum experience and educational background would be 5 years with at least an MS. in E.E. or Physics. A Ph.D. degree would be preferred with strong interests in electronics, theoretical physics or mathematics. Forward resumes to Mr. R. D. Williams, Employment Mgr., P. R. Mallory & Co. Inc. 3029 E. Washington St., Indianapolis, Ind.

ANALYST

Research and consulting in fields such as transportation, logistics, equipment investment, inventory control, marketing, operations research, data processing. Educational background in economics, transportation, mathematics, statistics, engineering. United Research, Inc., 808 Memorial Dr., Cambridge, Mass. Mrs. Paulsen, Personnel Director.

OPENINGS AT:

THE UNIVERSITY
OF MICHIGAN
Radiation
Laboratory

The Radiation Laboratory's efforts in plasma physics include high density and low density plasmas, using plasma diagnostic techniques for the design of instrumentation to learn about the possible ionospheres of other planets, such as Venus. Analyses of possible plasma radiation from ionospheric trails, shock fronts and flame fronts are being conducted. This work is primarily in theoretical physics.

We are seeking scientists with the Ph.D. degree or with comparable significant experience in the above or closely related fields of research.

Pleasant Mid-West location with liberal fringe benefits. Salary commensurate with abilities and background.

CREDIT
CREDIT CARD

To the ELECTRONIC ENGINEER who neglected to MARRY THE BOSS' DAUGHTER:

Don't bother telling us how it happened . . . we almost know. It was Spring—or Fall, no matter—and there you were, alone with That Other Girl. You couldn't have been thinking of your professional future because you'd had to explain to her dad that you didn't drive a locomotive. But she was lovely, desirable and it seemed unthinkable not to share your breakfast Wheaties with her the rest of your days. So, of course, you married her instead of the boss' daughter and your father-in-law turned out to be a grand guy even though he now tells people proudly that you make TV sets or something.

Which pretty much leaves your career up to *you,* doesn't it?

We have some advice for you; we'll not guarantee that it's impartial, but check it for logic anyway: Look for a leading electronics corporation which is essentially an engineering firm, where not only your immediate supervisors but top management will be engineers. Being engineers, they're more likely to recognize ability and to reward achievement *fairly and impartially.* It figures, we think, that where there's an atmosphere of mutual confidence, respect and understanding you'll realize your maximum potential at least a little sooner and more surely.

You may be pretty sure that Bendix, Kansas City, meets the specifications outlined above or instead of mentioning them at all we'd probably follow the crowd by speaking only vaguely of "opportunity" and "challenge." You have criteria of your own . . . measure Bendix with them and let us help you if we may.

P.S. **That girl you did marry will like Kansas City. So will you and the children. Practically everyone does.**

Mail brief confidential resume to MR. T. H. TILLMAN, BENDIX, BOX 303-OX, KANSAS CITY, MO.

LONG TERM AEC PRIME CONTRACTOR

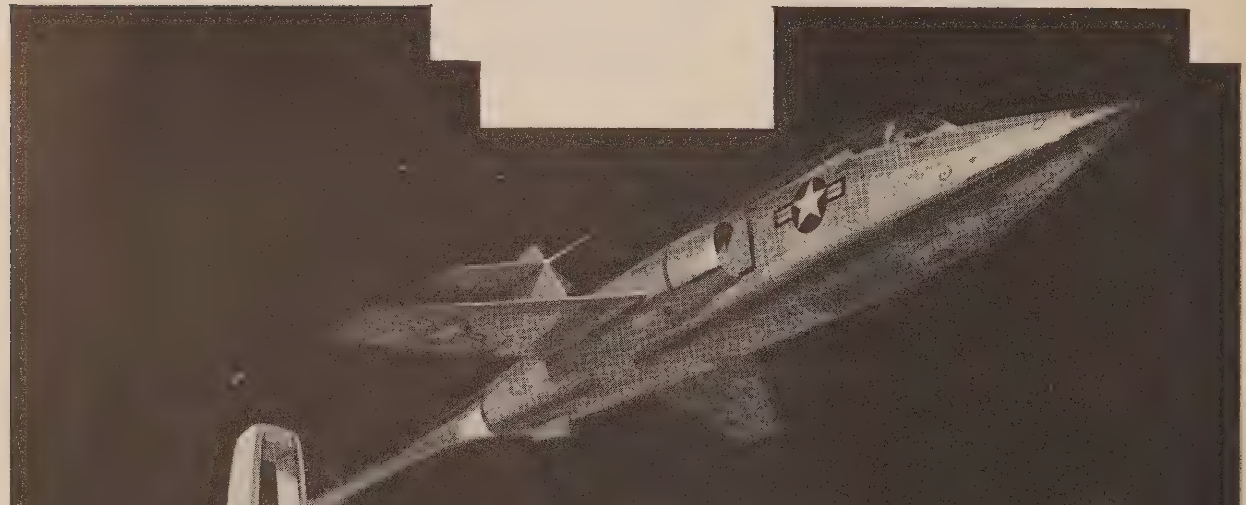
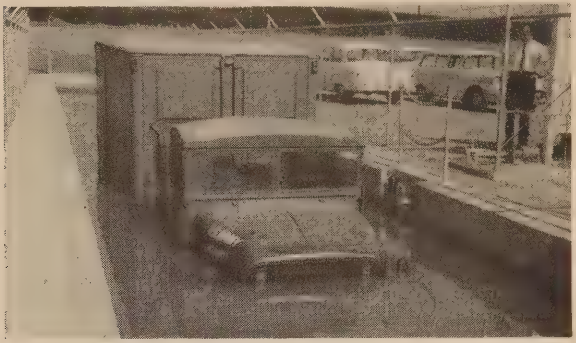
AVIATION CORPORATION
KANSAS CITY DIVISION

How to thread a needle



The Fording Test *is typical of the tough environmental tests imposed upon advanced electronic equipment designed and produced by Hughes Fullerton engineers.*

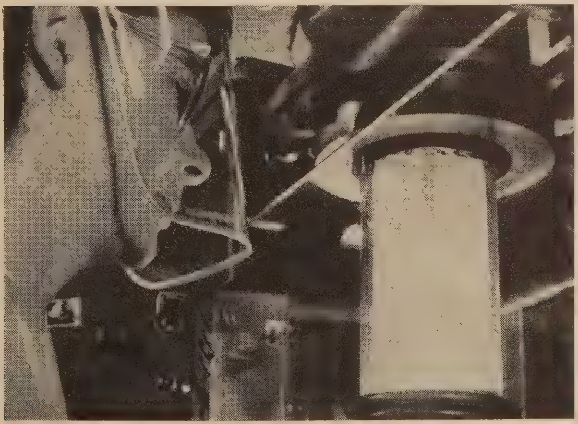


in the dark

TARAN (Tactical Attack Radar and Navigator) is typical of the important new electronic systems developed by Hughes—in an atmosphere famed for its engineering orientation.

Hughes engineers have designed this system to enable pilots to fly blind at very low altitudes in any kind of weather—and actually deliver any kind of armament at tactical targets.

TARAN's amazing abilities are based on several major electronic advances developed by Hughes engineers: A radar system with several times the range and azimuth resolution of current radars. An Automatic Navigation and Display System which pinpoints position continuously and automatically corrects for any navigational deviations. A unique terrain clearance indication warns the pilot of any obstacles when flying at low altitudes. A radar antenna utilizing electronic rather than mechanical lobing.



Molten Ladle *of silicon is watched during first step in the precise manufacture of Hughes semiconductors, just one of the Hughes commercial activities.*

Other Hughes activities provide similarly stimulating outlets for creative engineers. A few representative project areas include: advanced data processing systems, molecular electronics, advanced 3-D surface radar systems, space vehicles, nuclear electronics, ballistic missiles, infrared devices—and a great many others. The commercial activities of Hughes have many interesting assignments open for imaginative engineers to perform research, development, manufacturing of semiconductors, electron tubes, and microwave tubes.

Whatever your field of interest, you'll find Hughes' diversity of advanced projects gives you widest possible latitude for professional and personal growth.

Newly instituted programs at Hughes have created immediate openings for engineers experienced in the following areas:

- Electroluminescence
- Infra-red
- Solid State Physics
- Digital Computers
- Reliability & Quality Assurance
- Systems Design & Analysis
- Equipment Engineering
- Microwave & Storage Tubes
- Communications Systems
- Inertial Guidance
- Field Engineering
- Circuit Design & Evaluation

Write in confidence to Mr. R. A. Martin
Hughes General Offices, Bldg. 6-E4, Culver City, Calif.

HUGHES AIRCRAFT COMPANY
Culver City, El Segundo, Fullerton, Newport Beach,
Malibu and Los Angeles, California; Tucson, Arizona

SENIOR MICROWAVE ENGINEER

You will be given system responsibility for the development of new concepts in the generation, propagation and radiation of microwave power for heating, cooking and curing purposes, in numerous commercial and industrial applications. (Raytheon is one of the few electronics companies whose staff includes systems, advanced development, and design engineers in these fields).

You must have a BSEE or equivalent and should have 8 years of broad design or advanced development experience in the microwave field in order to handle the planned assignments. (Experience in radar development, for instance, or DC power generators or magnetrons.) Since we're looking for an exceptional individual—who will be rewarded accordingly—the deciding factor will probably be your creativeness and ingenuity, as evidenced by: patent disclosures; significant publications; or descriptions of accomplishments not formalized by patents or publication.

MICROWAVE LICENSEE ENGINEER

You will serve as liaison between Raytheon and licensees, assisting in the design of microwave cooking units for these licensees' commercial ovens. This will involve working with the licensees' design engineers to solve such problems as heat, sanitary considerations, microwave distribution, wave modulation, insulation and cost reduction. You will also help translate licensees' suggestions into product improvements.

You should be a senior-level electronics engineer with a BSEE or equivalent and should have 5 years' applicable experience. Background in design of test equipment, high-power modulators, or commercial microwave equipment is especially useful, as is knowledge of magnetrons, underwriters' requirements and FCC regulations. Basically, we're looking for a top design and sales engineer (travel will be limited, however) so salary is commensurate—that is, excellent.

Both positions are in the suburban Boston area and offer attractive cultural, educational and recreational opportunities. Relocation assistance is available. Please phone collect (BIgelow 4-7500) or forward your detailed resume to Mr. Paul R. Alexander, Manager of Professional Personnel, Commercial Apparatus & Systems Division, Raytheon Company, Watertown, Massachusetts.

COMMERCIAL APPARATUS & SYSTEMS

PROFESSORS

Electrical Engineering Faculty in new and rapidly expanding university has openings at senior levels. Duties include graduate teaching and research. Immediate opening for professor interested in developing courses and participating in research in logic, switching and computery. Ph.D. essential. Salary up to $13,000. Apply Chairman, Electrical Engineering Department, University of Waterloo, Waterloo, Ontario.

Positions Wanted

By Armed Forces Veterans

In order to give a reasonably equal opportunity to all applicants and to avoid overcrowding of the corresponding column, the following rules have been adopted:

The IRE publishes free of charge notices of positions wanted by IRE members who are now in the Service or have received an honorable discharge. Such notices should not have more than five lines. They may be inserted only after a lapse of one month or more following a previous insertion and the maximum number of insertions is three per year. The IRE necessarily reserves the right to decline any announcement without assignment of reason.

Address replies to box number indicated, c/o IRE, 1 East 79th St., New York 21, N.Y.

ENGINEERING TEACHER

B.S. and M.S. in E.E. 2 years industrial research, 2 years applicable military, and 4 years full-time teaching on the faculty of a major east coast university. Desires position of permanence with good family living conditions. Summer income opportunity desirable. Available June 1960. Box 2052 W.

ELECTRICAL ENGINEER

B.S. in physics, graduate work in E.E.; 7½ years experience in electronics of which 3½ years is in commercial data processing. Have published articles and hold patents in electronics. Desires overseas position. Box 2053 W.

ENGINEER

BSEE., extensive antenna and R.F. experience, design and project supervision. Broad background includes sales and engineering management, contract negotiations. Desires position as General Manager of antenna company, or participant in ownership management of antenna consulting firm or small growing company. Box 2054 W.

COMPONENTS ENGINEER

E.E. degree. 10 years solid experience in electromechanical components—development, evaluation, application and standardization. Desires a challenging, responsible position in a supervisory capacity, New York, Long Island area preferred. Box 2055 W.

ELECTRONIC FIELD ENGINEER

Graduate engineer, BSEE., several years experience, age 32, fair health, seeking position as electronic engineer—sales engineer, field engineer, coordinator customers' technical requirements either commercial or military customers, or supervisor equipment installation and installation checkout. Preparation with company training course desirable. Box 2056 W.

An Invitation To Join ORO . . . Pioneer In Operations Research

Operations Research is a young science, earning recognition rapidly as a significant aid to decision-making. It employs the services of mathematicians, physicists, economists, engineers, political scientists, psychologists, and others working on teams to synthesize all phases of a problem.

At ORO, a civilian and non-governmental organization, you will become one of a team assigned to vital military problems in the area of tactics, strategy, logistics, weapons systems analysis and communications.

No other Operations Research organization has the broad experience of ORO. Founded in 1948 by Dr. Ellis A. Johnson, pioneer of U. S. Opsearch, ORO's research findings have influenced decision-making on the highest military levels.

ORO's professional atmosphere encourages those with initiative and imagination to broaden their scientific capabilities. For example, staff members are taught to "program" their own material for the Univac computer so that they can use its services at any time they so desire.

ORO starting salaries are competitive with those of industry and other private research organizations. Promotions are based solely on merit. The "fringe" benefits offered are ahead of those given by many companies.

The cultural and historical features which attract visitors to Washington, D. C. are but a short drive from the pleasant Bethesda suburb in which ORO is located. Attractive homes and apartments are within walking distance and readily available in all price ranges. Schools are excellent.

MARKETING DIRECTOR-SALES MANAGER

Desires to relocate. Connecticut preferred. Excellent background in building and managing electronic sales organizations. Experienced in directing all phases of marketing activities. Age 37, married. Resume furnished on request. Box 2061 W.

UNIVERSITY ADMINISTRATOR

11 years college administration and teaching experience, plus industrial research, electronic design and development. Currently conducting year's research in industry. Have directed grant programs, technical adult education, research, taught undergraduate and graduate. BS. and MS. in E.E. Married. Age 36. Excellent references. Interested in challenging college position. Prefer Rocky Mountain area. Box 2062 W.

ELECTRICAL PATENT POSITION

BEE. Polytechnic Institute of Brooklyn 1958. Coast Guard officer desires position in Patent branch of organization located near a law school. Patent, law school and engineering experience. Box 2063 W.

ELECTRICAL ENGINEER

BSEE. 1957. 1/Lt. Sig. C. 1½ years as Project Officer at WSMR, New Mexico. Experience in the field of guidance and countermeasures of missiles. Interested in obtaining a LL.B. Desires position which requires an engineering and legal combination with management opportunities. Box 2072 W.

ELECTRONICS ENGINEER

European assignment desired in western or southern Europe in management, technical or liaison area. 15 years experience R and D, both civilian and military, in communications, electronic countermeasures, television and missile electronics. Considerable supervisory experience. BEE. and MEE. degrees. Box 2073 W.

ELECTRONICS ENGINEER

BS. in Physics. MSEE. 5 years experience in transistorized digital computer circuit design and radar-computer systems. Single, age 28. Desires position in western Europe. Box 2074 W.

ENGINEERING MANAGER

Communications systems engineering of telephone, radio relay, microwave, HF and SSB Systems. 20 years military experience all phases applied engineering, siting, installation, operation and maintenance. Performed Staff Engineering assignments at Pentagon and major command levels. Currently Deputy Chief, Maintenance Engineering & Test Branch, multi-billion dollar air defense project office. Supervisory experience with over 500 personnel. 21 months military electronics schooling plus BBA. and MBA. and 14 months training with industry. Senior Member IRE. Desires managerial position with growth potential. Available August 1960. Box 2075 W.

ENGINEER

BS. graduate with electronics major desires position in component or systems design engineering. Have pilot license. Prefer Minnesota or midwest area. Box 2076 W.

ELECTRONIC ENGINEERS and INDUSTRIAL RESEARCH PHYSICISTS

Electronics • Optics • Sonics
Instrumentation • Automation • Measurements

If you are an electronic engineer or physicist and have broad technical interest in any of the above fields, then the Physics Department of Continental Can Company offers you a unique opportunity for interesting non-defense work and professional growth.

THE POSITIONS

We have openings for both recent graduates and more experienced individuals and one, with the title of Genral Physics Laboratory Dirctor, for an outstanding man who has demonstrated considerable creative ability.

THE WORK

We are pioneering long-range and radically new processes and products arising out of the company's major position in high-speed fabrication of metal, glass, paper, fiber, cork and plastic containers, and other products. In addition, we render consulting services to other divisions.

THE BENEFITS

Salary structure is truly excellent, and there are numerous benefits including company-paid hospitalization and life insurance, relocation assistance. Staff members are encouraged to keep ahead in their profession.

THE LOCATION

The division's new laboratories are located within easy reach of the University of Chicago, The John Crerar Library, Argonne National Laboratory, and the finest southern and western residential suburbs.

You are invited to investigate these opportunities at Continental Can Company in complete confidence—and without obligation. A few minutes now can mean a jump of years in your professional progress.

Please write or call collect to

GROW with Kollsman

Kollsman's leadership and continuing growth in the field of automatic navigation and flight instrumentation assures excellent opportunities for qualified men. Send resumes to Mr. T. A. DeLuca.

Opportunities in:

FLIGHT DATA INSTRUMENTS & SYSTEMS
Senior Project Engineers, EE & ME

For aircraft and missile instrumentation. 5 to 10 years project experience in precision electromechanical devices.

AUTOMATIC ASTRO TRACKING SYSTEMS
Project Engineers, EE

For automatic astro tracking systems. Up to 5 years related experience.

STAFF ENGINEERS & SPECIALISTS

a. Experience in the research and development of transistors in servo, digital and instrumentation application. Minimum 3 years experience desired in transistor circuit design for military applications.

b. Experienced with IR to UV radiation properties and applications, noise theory and detectors.

c. Optics — IR through visual optical design, lens design, materials.

d. Digital computers — logic or packaging experience.

e. Theoretical mechanics — inertial and trajectory studies.

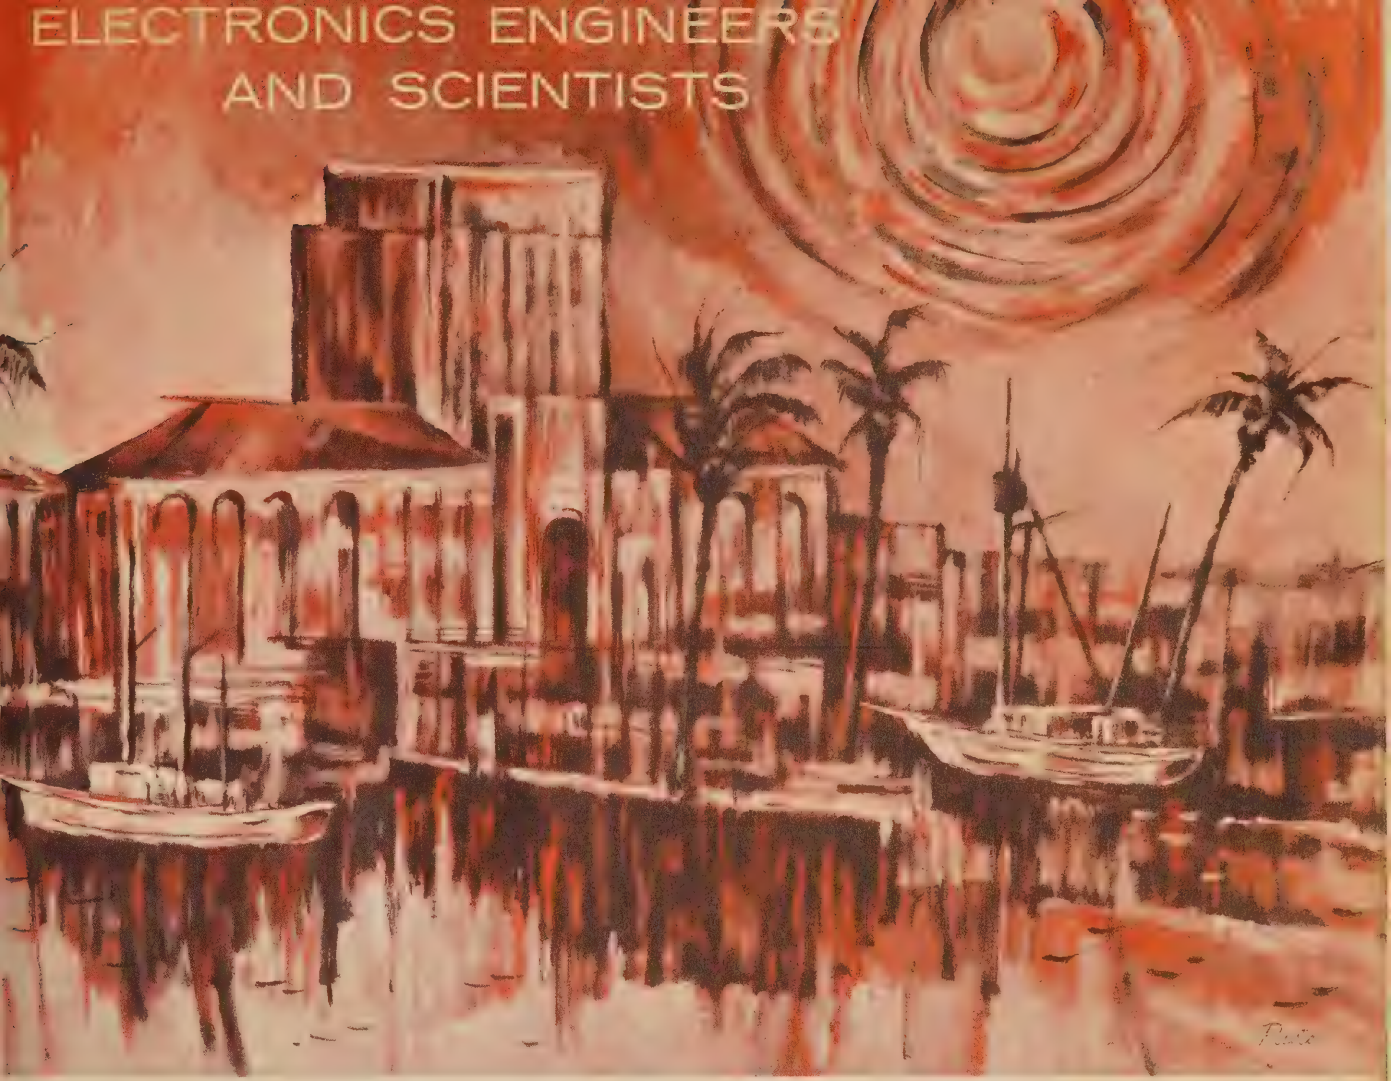
ELECTRONICS ENGINEERS AND SCIENTISTS



San Diego Civic Center, an original painting by Sammy Pasto, Convair/San Diego artist

A newly formed electronics organization at Convair/San Diego is now being staffed, offering truly unusual opportunities for high level electronics engineers and scientists.

Electronics engineers and scientists who have demonstrated a level of ability beyond mere competence, will discover the technical challenge they desire at Convair/San Diego Electronics. This newly formed department is now being staffed and affords a truly unusual opportunity to participate in a formulative effort while enjoying the stability of association with a well established company.

Significant research and development is now in progress on infrared and optical systems, advanced radar and communications techniques, space vehicle and missile guidance, submarine detection systems, anti-satellite and AICBM systems, and space weapons systems.

In addition to advanced programs, electronic engineers and scientists at Convair/San Diego Electronics enjoy unsurpassed climate, fine schools and advanced education facilities, and a progressive cultural environment. For further details, please see the next page.

- Aircraft Antenna Engineers
- Microwave Antenna Engineers
- Microwave Engineers and Physicists
- Radome Engineers
- Electronic Production Engineers
- Electronic Systems Engineers
- Electronic Project Engineers
- Research Engineers (Infrared)
- Ultrasonic Engineers (ASW)

For more complete information, including a copy of a new brochure which explains these activities in more detail, simply complete the form below. This entire page may be removed from the magazine, folded, sealed and mailed in complete confidence.

THE ARTIST — Sammy Pasto, Convair-San Diego artist whose painting appears on the preceding page, is a native of Boston. He studied at the New England School of Art and moved to California following World War II. Presently working as an illustrator at Convair-San Diego, Pasto has received broad recognition for his work in fine arts. He has had one-man shows in New York, Philadelphia and Los Angeles and his work has been accepted in most juried West Coast art shows. For a change of pace, Pasto plays clarinet in a prominent Dixieland jazz band in San Diego.

PROFESSIONAL EMPLOYMENT INQUIRY — This information will enable the professional staff at Convair/San Diego to make a preliminary evaluation of your background. A personal interview can be arranged in your city by appointment. Every completed inquiry will be acknowledged.

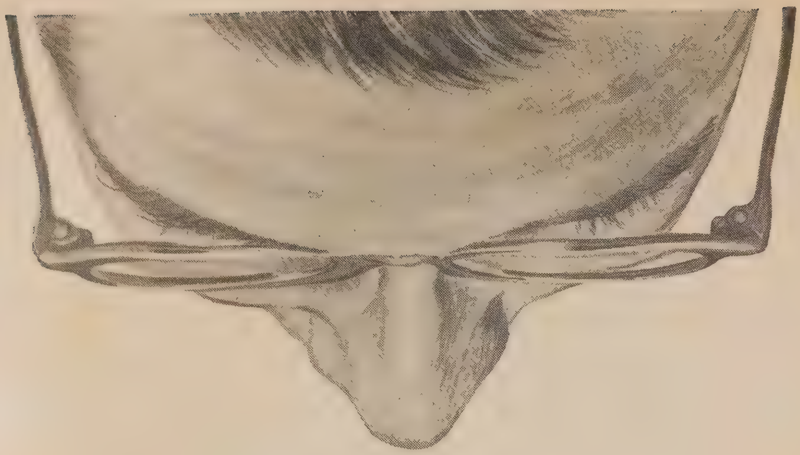
LIGHT MILITARY ELECTRONICS DEPARTMENT

GENERAL ELECTRIC

FRENCH ROAD, UTICA, NEW YORK



Look beyond the obvious . . .

. . . as you consider *your* future in the electronics industry. First, what is the obvious? It's obvious that you're in demand. You don't have to worry about getting your material wants satisfied.

But, when you look beyond the obvious, you realize that you want something more than simple "want satisfaction" out of your career. You want *pride*—pride in the importance of your personal, *individual* contribution.

At Melpar, where we are now working on 120 advanced defense and space exploration projects, we have significant opportunities for the professional engineer or scientist who wants to be proud of his contribution to advancing the state of electronic art.

Senior-level positions are available in the following areas at this time:

Reconnaissance Systems
Airborne Equipment
Ground Data Handling Equipment
Simulation & Training Systems
Communication & Navigation Systems
Ground Support Equipment
Detection & Identification Systems
Antenna & Radiation Systems
Physical Sciences Laboratory
Production Engineering
Quality Control
Field Service Engineering

THEY BUILT AN ELECTRONIC MARVEL WHERE THE JUICY ORANGES GROW

Starting from scratch, the men of Martin-Orlando designed and built a package of over 290,000 electronic parts—the Missile Master. Now operational, Army's Missile Master is the nation's first and most reliable (99.2%) air defense control system.

Production is continuing now down where oranges ripen in almost perpetual sunshine. It's a land where engineers and scientists bring more to their work because they can *relax*—at the nearby shore . . . or any of 54 lakes . . . on fairways . . . tennis courts . . . or shady patios. From these men have come:

Bullpup—operational guided missile for the Navy (GAM-83A in R&D for the Air Force)—so reliable it's handled as an ordinary round of ammunition. *Lacrosse*—now operational — is the Army's most accurate surface to surface missile. *Pershing* — Army's selective combat range artillery missile —now in advanced development.

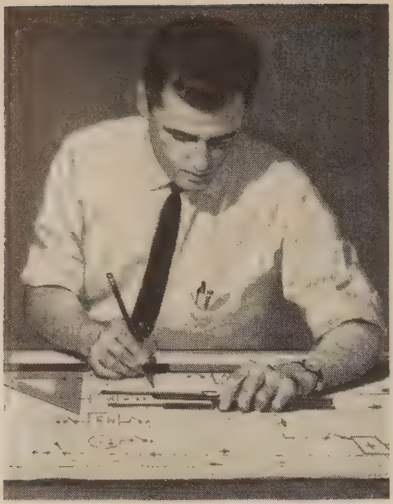
Wouldn't you like to work in one of America's most advanced electronic and missile centers down where the big careers and the juicy oranges grow? Take the first step now.

Write: C. H. Lang, Director of Employment, The Martin Company, Orlando 2, Florida, for your copy of the descriptive booklet, "Portrait of a Missile Maker."

CURRENT OPENINGS for engineers in these areas: ground and airborne electronics • advance design • systems • aerodynamics • quality and test • reliability • electronics manufacturing . . .

Work in the Climate of Achievement

MARTIN
ORLANDO



digital computer designers

The Crosley Division of Avco Corporation has openings for electronic engineers with from two to ten years' experience for unusually responsible positions involving digital computer and data processing equipment design.

At Crosley, all projects offer engineers of talent and capability unlimited challenge and definite authority. An alert, aggressive management team provides maximum support and backing to each of the outstanding professional teams working on the frontiers of data processing for industrial systems.

Now is your opportunity to grow your own career in this new and exciting field. Experienced personnel can choose:

- transistorized circuit design
- digital systems design
- logic design

For complete information, write or call:

Engineers and Physicists

Your talent and time are worth more to you —and to your family—in Minneapolis

Talent and time are man's most precious tools—but, unfortunately, they are also his impediments.

If you suspect that you could put your talent and time to more productive and rewarding work, investigate opportunities at General Mills, in Minneapolis. We respect creative freedom, encourage innovation, recognize and appreciate professional competence. In short, we provide the environment that brings out the finest talents in engineers and scientists. And then we give these creative people rein to ply their talents against intriguing problems in fields that interest them most.

Time? Time in the laboratory. Time with your family. Ninety percent of our people live within 25 minutes from work. A short drive takes them to some of the best hunting, fishing and camping sites anywhere. Some of them live right next to a park, lake or golf course.

At General Mills, in Minneapolis, you have time to know your family, yourself and your contribution to the future.

- Digital System Configuration
- Electronic Circuit Design
- Micro-wave Development
- Digital Computer Logic
- Electronic Packaging
- Advanced Pulse and Video Circuit Development
- Advanced Inertial Navigational System Development
- Optical and Infra-Red Equipment Engineering

MECHANICAL DIVISION General Mills

Extending existing modulation systems to make more space available in the spectrum, and possibly even broadening the useful spectrum . . . this is a fundamental problem in modern communications. It is the problem to which ITT Laboratories is devoting intensive effort.

At the low end we're designing a new type antenna for very low frequencies. With a conventional antenna this would require a tower more than three miles tall. On the top side — at the high end — we're making radiation pattern surveys for the super high frequency bands. Here the entire antenna consists of a few millimeters of number eighteen copper wire. We're matching these efforts with advances in componentry . . . for instance, the parametric amplifier and now the ingenious ferroelectric converter which converts solar heat to high voltage electricity to power new satellite communications.

If you are a communications engineer who would like to be associated with some of the most significant programs in modern communications development . . . if you would like to work with men who are stretching the spectrum toward direct current at the bottom and the cosmic rays at the top . . . write Manager Professional Staff Relations . . . tell him your interests, your background and the kind of work you would like.

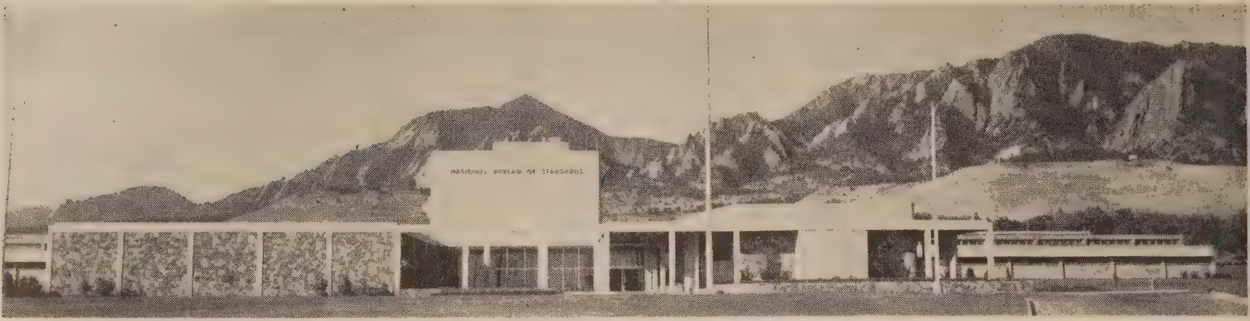
KNOWLEDGE—*Our Challenge!*



BOULDER LABORATORIES, THE NATIONAL BUREAU OF STANDARDS
Boulder, Colorado

● By performing basic and applied research in radio propagation, radio standards, radio systems, and cryogenic engineering, **PHYSICISTS, MATHEMATICIANS, and ELECTRONIC ENGINEERS** can contribute to the NBS goal of leadership in these fundamental areas in an atmosphere which enhances opportunities for individual advancement in professional status.

● Close to the University of Colorado, large city (Denver) advantages, and mountain recreation (winter and summer), the Boulder Laboratories Professional Staff is a research group, moderate in size but tremendous in the scope of its national and international activities.

● Positions are filled in accordance with applicable U. S. Civil Service procedures. Starting salaries range from $4,490 to $12,770 per year. Address inquiries to:

Roy W. Stockwell, Jr.

analytical, systems, components engineers

CHECK THESE OPENINGS IN FLIGHT CONTROLS WITH HONEYWELL AERONAUTICAL

Honeywell introduced the first successful electronic autopilot in 1941—the C-1 of World War II. Since, we have produced more flight control systems than any other company and have developed concepts in flight controls that are now standard in this field. Today, most top aircraft and missiles are equipped with Honeywell flight controls. Honeywell's Flight Control Systems Group has expanded steadily and now has openings for the following:

ANALYTICAL ENGINEERS—must be capable of simulating (mathematically on paper or computers) characteristics and problems in missiles and aircraft control, stability, and control systems. Should have good math backgrounds with analog computer experience.

SYSTEMS ENGINEERS—should be capable of interpreting analytical results into navigation, guidance, or flight control systems. Should be electrical engineers experienced in systems—ideally, with experience in flight control in the aviation industry.

COMPONENTS ENGINEERS—should be electronics men with emphasis on transistor circuitry. Will be responsible for designing components which go into the system. Must have circuitry design experience.

If you are a qualified engineer interested in one of these areas, we'd like to hear from you. Just drop a line including pertinent information on your background, interests, and accomplishments to Mr. Bruce D. Wood, Dept. 549,

Honeywell
AERONAUTICAL DIVISION
1433 Stinson Blvd. N.E., Minneapolis 13, Minnesota

To explore professional opportunities in other Honeywell operations coast to coast, send your application in confidence to H. K. Eckstrom, Minneapolis 8, Minnesota.

Pioneer V
Paddlewheel Planetoid
Is Vaulting
Through Unexplored Space
Toward The
Orbital Path of Venus

At this moment Pioneer V, one of the most advanced space probe vehicles ever launched, is on a course toward the path of Venus—26 million miles from earth. Blasted aloft March 11 by a Thor Able-4 rocket booster, this miniature space laboratory will reach its destination in about 130 days.

The project, carried out by Space Technology Laboratories for the National Aeronautics and Space Administration under the direction of the Air Force Ballistic Missile Division, may confirm or disprove long-standing theories of the fundamental nature of the solar system and space itself.

Energy from the sun—captured by almost 5,000 cells mounted in the four paddles—is used to supply all of the electrical power to operate the sophisticated array of instrumentation packed into the 94-pound spacecraft which measures only 26″ in diameter.

By combining a phenomenal digital electronic brain (telebit) with a powerful radio transmitter inside the satellite, STL scientists and engineers expect to receive communications from Pioneer V at their command over interplanetary distances up to 50 million miles.

STL's technical staff brings to this space research the same talents which have provided over-all systems engineering and technical direction since 1954 to the Air Force missile programs including Atlas, Thor, Titan, Minuteman, and related space programs.

Important positions in connection with these activities are now available for scientists and engineers with outstanding capabilities. Inquiries and resumes are invited.

SENIOR ENGINEERS

Your creative performance in advanced assignments at Boeing-Wichita offers unique opportunities for professional and personal recognition. Among the high-level openings in an expanding, long-range program of new product design and development are these specific positions:

ELECTRONICS

BOMBING AND GUIDANCE SYSTEMS RESEARCH ENGINEERS to analyze and propose new systems and improvements for present systems of digital or analog bombing, navigational or search radar, doppler radar and associated flight test instrumentation; and to plan laboratory and flight tests and evaluate and analyze test results, using well-equipped electrical and computer engineering laboratories.

ELECTRICAL INSTRUMENTATION ENGINEERS to plan, design and develop instrumentation for new types of vehicles; monitor installation of test equipment, methods of recording such as electronic tracking components; and evaluate test data such as measurement of surface temperatures, heat transfer coefficients, pressure vibrations and acceleration strains as related to new product airframe design and testing.

COUNTERMEASURES SYSTEMS RESEARCH ENGINEERS to conduct research, analyze and develop improved techniques in the field of infra-red, ultra-violet and optics; including critical analysis of existing methods and knowledge required to advance the state-of-the-art applicable to defense and offense weapons.

PHYSICAL SCIENCES

ACOUSTICS AND ELECTRO-PHYSICS ENGINEERS to determine and predict sound levels to which aircraft structures, equipment and flight crew compartment are exposed; to develop noise suppression techniques, design test models; and experiment with transmission characteristics of new materials.

For immediate action on these or similar senior level openings which you are qualified to fill, contact Mr. Melvin Vobach, Boeing Airplane Company, Wichita 1, Kansas.

NEW OPPORTUNITIES IN

LOW-NOISE AMPLIFIERS SEMICONDUCTOR DEVICES
ELECTRON-BEAM DYNAMICS MICROWAVE CIRCUITS
TV AND RADIO RECEIVER DESIGN ENGINEERS

AT ZENITH®

Chicago, Ill., and Menlo Park, Calif.

The continuing expansion program at Zenith has created new opportunities for engineers with experience in the above fields.

The fast-wave **electron-beam parametric amplifier,** conceived at Zenith, has opened up challenging new fields for research and development activity from UHF to SHF bands. Broad company interests in the microwave-tube area provide fertile atmosphere for original ideas and individual initiative.

An expanding research program in new fields centered around **compound semiconductors** provides opportunities for individuals with backgrounds in the solid-state art. Development of special devices for highly specific purposes, in collaboration with applications engineers, represents another area of active interest in the semiconductor field.

Positions are now available in the Research Department at Chicago; some openings are available in the San Francisco Bay Area. Congenial small-group atmosphere prevails, with all the advantages of a large, progressive company.

Interested applicants please contact:

Design for Personal Progress

Let Abbott's be your Personal Agent in presenting your qualifications to the nation's foremost employers of engineers and scientists. You'll find this specialized service extremely effective in placing you where your ability, background and effort will yield the greatest rewards.

If you are placed through us, our clients will pay all expenses and our service charges.

Salary Ranges—$10,000-$25,000

- DIRECTOR OF ENGINEERING—Commercial and military communications
- ENGINEERING MANAGERS—Device development, radar systems
- SECTION HEADS—Computers, navigation systems, components
- STAFF ENGINEER—Infrared systems
- ENGINEERING SPECIALISTS—PhD, microwave devices, infrared
- SENIOR ENGINEERS — Radar computers, navigation systems
- DESIGN & DEVELOPMENT ENGINEERS—Tubes, gyros, semi-conductors, transducers, systems, circuitry radar, missiles, digital computers

Recognized for over 37 years, among leading companies, for confidential placement of engineering, scientific and administrative people.

Explore new areas at IBM in design and development of semiconductors

Many new designs in IBM circuits and systems require the latest advances in the semiconductor field. The program includes theoretical and experimental studies in the most advanced semiconductor devices and technology. An example of an original IBM development is the NPN high-speed drift transistor for logical switching and high-power core driving. These programs are opening up new opportunities for high-level professional people. Related areas where opportunities exist include: applied mathematics and statistics, circuit research, logic, cryogenics, optics, phosphors, magnetics, microwaves, and theory of solid state.

A career with IBM offers advancement opportunities and rewards. You will enjoy professional freedom, comprehensive education programs, and the assistance of specialists of diverse disciplines. Working independently or as a member of a small team, your contributions are quickly recognized. This is a unique opportunity for a career with a company that has an outstanding growth record.

QUALIFICATIONS: B.S., M.S., or Ph.D. in one of the physical sciences—and proven ability in the field of semiconductors.

For details, write, outlining background and interests, to:

Senior
Research Scientists
& Engineers

to help solve
an important
communications
problem

The problem . . . to define the parameters and establish feasibility of a long-range, ECM-proof, single or multiple path communications system capable of negligible degradation and an ultra-high degree of reliability while operating in a constantly changing environment.

The solution, at present, is difficult . . . all known techniques, individually or multi-plexed, would provide only marginal performance.

Research Scientists and Engineers with advanced degrees who feel they can contribute new insight, new concepts, and the application of new techniques to the establishment of this vitally important system are invited to forward their confidential inquiry to:

Operating from a growing research-base

STROMBERG-CARLSON

expands 60% in 5 years

Offers new opportunities across entire organization

Throughout its 65 year history, Stromberg-Carlson has adhered to a two-pronged policy of simultaneously:

1. providing the highest standards of engineering performance in its products and programs
2. building its future capacities for still more advanced engineering and scientific achievements through research

This policy has brought steady growth to the company and long term career stability to its professional staff. After its merger with General Dynamics in 1955, it became possible to step up research efforts substantially. The ensuing 5-year period has been characterized by marked acceleration in personnel (60%) with the professional staff growing at an even faster rate. The cumulative results of this dynamic half-decade now enable Stromberg-Carlson to embark on a new period of expansion, with a DIVERSITY of opportunities open, across the entire organization, on a DIVERSITY of commercial and military projects.

If you are interested in, and qualified for one of these positions, send a complete resume to Technical Personnel Department.

New Positions are immediately available on both Commercial and Defense Projects:

RESEARCH SCIENTISTS

Advanced degree EE's and Physicists to handle conceptual studies in areas of solid state circuitry and semiconductors; molecular electronics; hydro-acoustics; digital data transmission; and speech analysis. Also openings for advanced degree mathematicians for study projects in information theory and related areas.

DEVELOPMENT ENGINEERS

Current openings at intermediate through technical supervisory levels for men experienced in communications systems; microwave circuit design; data handling and display equipment; air navigation control instrumentation; automatic test equipment and underseas warfare.

CONSUMER PRODUCT DESIGN ENGINEERS

Intermediate to senior level openings for engineers to work on stereo, hi-fi, auto radio and commercial sound systems, with experience in audio and R. F. field utilizing transistorized circuitry. Also openings for engineers experienced in design of special switching and electro — mechanical circuitry for telephone systems.

also positions for:

TECHNICAL WRITERS, CONTRACT ADMINISTRATORS, TEST ENGINEERS, STAFF ADMINISTRATIVE ENGINEERS.

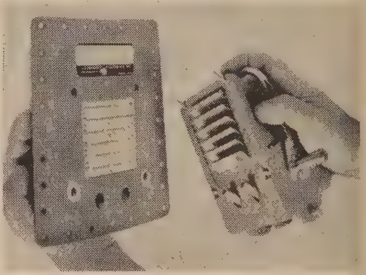
Umbilical Connector

Automation Electronics, Inc., an operating division of **Arnoux Corp.**, 11924 West Washington Blvd., Los Angeles 66, Calif., released data on its umbilical connectors which have been under development for some months. Already in use on an intermediate range missile, the unit is small, lightweight, and of integrated construction. The umbilical also features a mating and unmating mechanism so that the whole operation may be accomplished without the use of any tools.



This particular design provides for 300 individual contacts, each rated at 5 amperes and all are mounted in a space $2\frac{3}{4}$ inches square. The whole unit is sealed in a magnesium aluminum casing which matches a cutout in the missile skin. There are two fluid lines, each capable of carrying three gallons per minute with a maximum pressure drop of 6 psi. Disengagement is accomplished in two ways: normal motion of the missile disengages these contacts; and the plug may also be removed manually without missile motion.

The contacts are Multifilar and consist of heat-treated beryllium copper spring wires, which are silver-flashed and gold-plated. This design provides for high resistance to corrosion. Another advantage of this kind of contact is that a great number of disconnects are possible with very little degradation of the electrical contacts.

Further information may be obtained by writing to Arnoux.

Miniature Potentiometers

A new series of $\frac{5}{8}''$ diameter miniature compact composition variable resistors i offered by **Chicago Telephone Suppl Corp.**, Elkhart, Ind. Series 200 can be furnished with or without attached switch i standard bushing mounted construction o in the more economical ear mounting. Resistance range is 250 ohms through 2. megohms linear taper, wattage rating watt through 100,000 ohms and 2/10 wat over 100,000 ohms at 55°C derated to n load at 85°C, voltage rating 750 vac bushing to terminals for 1 minute high pot tes and 500 vdc operating maximum, 35 vdc across end terminals and 280° rotatio without switch, 315° with switch. De

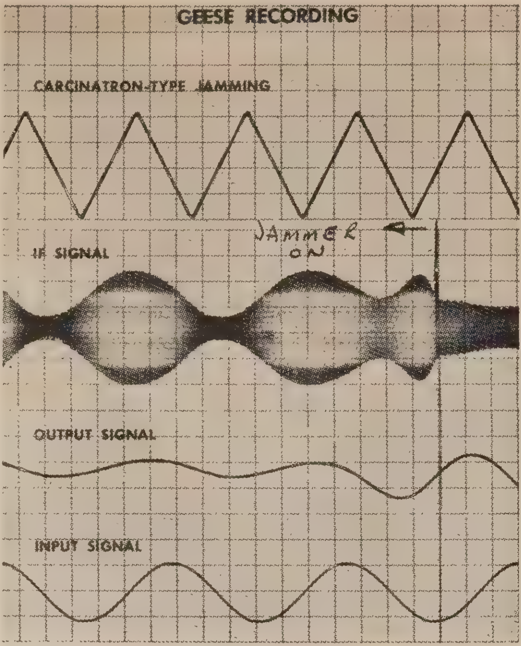
General Motors pledges
AC QUESTMANSHIP
2

AC Seeks and Solves the Significant—Inspired by GM's pledge to contribute heavily to our national defense, AC, an acknowledged leader in the new technology, plans to reach far beyond such accomplishments as AChiever inertial guidance systems. / This is AC QUESTMANSHIP. It's an exciting scientific quest for new ideas, components and systems . . . to promote AC's challenging projects in guidance, navigation, control and detection. / Mr. Jack Briner, AC Director of Field Service, believes his department's Career Development Program "offers young engineers world-wide opportunities in the practice of Questmanship." They learn a product from its technological theory through its operational deployment. Following this training, "they utilize their own ingenuity to support AC products in the field, with more effective technical liaison through training, publications, maintenance engineering, and logistics." / You may qualify for this special training, if you have a B.S. in the electronics, scientific, electrical or mechanical fields. Special opportunities also exist at AC for men with M.S. and Ph.D. degrees. If you are a "seeker and solver," write the Director of Scientific and Professional Employment, Mr. Robert Allen, Oak Creek Plant, Box 746, South Milwaukee, Wisconsin.

GUIDANCE / NAVIGATION / CONTROL / DETECTION / AC SPARK PLUG *The Electronics Division of General Motors*

SYSTEMS ENGINEERS AND SCIENTISTS

Almost any conceivable signal can be generated on GEESE; these signals can be carefully controlled in frequency, phase and amplitude, and their instantaneous relationship can be recorded. GEESE has the flexibility to fully evaluate advance radar, communications and guidance systems and the effects of various jamming and anti-jamming techniques.



EVOLVING LARGE-SCALE SYSTEMS CONCEPTS

AND DEVELOPING THE TOOLS THAT SPEED THEIR DESIGN CYCLE

Defense Systems Department is directing its technical capabilities toward the development of large-scale electronic systems. Inherent within this work program is the recognition, definition and solution of problems in every aspect of the systems technology.

To accomplish this ambitious task, a growing number of studies are being directed toward the development of unique tools that will aid in the design of superior systems in less time, at lower cost.

A recent contribution by Defense Systems Department in this technological area is GEESE (General Electric's Electronic System Evaluator). Utilizing advance computer techniques, it enables systems engineers to accurately predict, optimize and synthesize system performance prior to design.

GEESE is indicative of the scope of Defense Systems Department's involvement in the systems technology. Many programs offer systems-oriented engineers and scientists an opportunity to participate in new areas of long-term importance.

Senior members of our technical staff would welcome the occasion to discuss personally and in detail the career positions available with this growing organization. Address your inquiries in professional confidence to Mr. E. A. Smith, Box 4-F.

DSD DEFENSE SYSTEMS DEPARTMENT

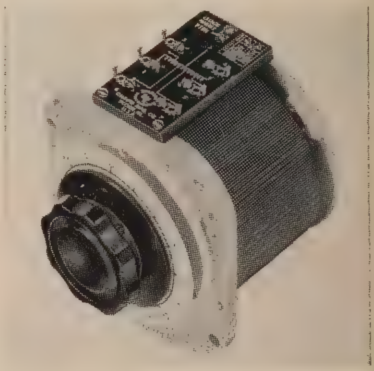
signed for commercial applications where space is at a premium. For applications requiring extremely compact control and SPST switch combinations, unique Type QS-200 combined switch and control in a single miniature molded housing. Base prices in 3000-9999 quantities for the various Series 200 constructions start at $160.42 M without switch and $316.93 M with switch. Delivery 4 to 5 weeks after sample approval.

Variable Transformers

Individual transformers operating from a single-phase, 240-volt line are now available from **Ohmite Manufacturing Co.,** 3696 Howard St., Skokie, Ill. Model VT8H is rated 3 amperes and at maximum setting will deliver line voltage (240v) or overvoltage (280v). Model VT8HN is the "no-overvoltage" type which will deliver just line voltage at maximum setting, but offers a current bonus in its output rating of 4 amperes.



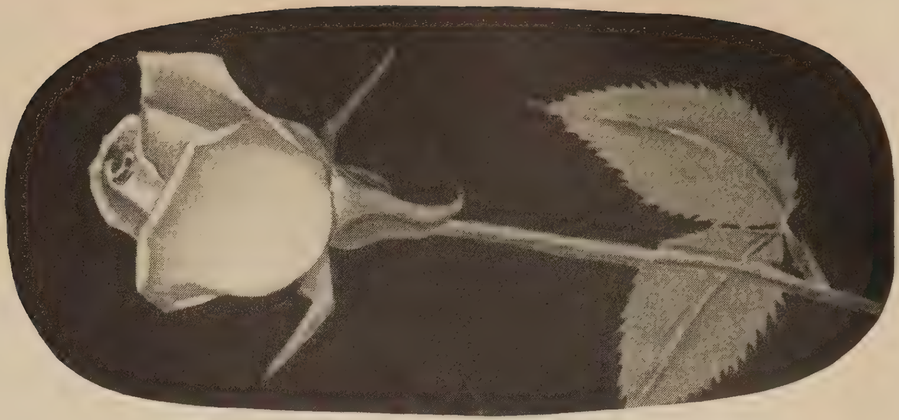
Both models are constructed on the same frame as Ohmite's popular VT8 series (ratings for 120-volt input types; 7.5 amperes with overvoltage; 10.0 amperes without overvoltage). The "high voltage" units afford the convenience of 240-volt, single-phase operation using a single unit instead of a ganged assembly. The 240-volt, single-phase operation can also be achieved with ganged assemblies of 120-volt input transformers where higher power output is desired.

The transformers have a tap which permits operation at 120 volts input with 280 volts output for the VT8H and 240 volts output for the VT8HN (some derating is required for output beyond 120 volts). These high voltage transformers can also be obtained in ganged assemblies to achieve 240-volt, 3-phase operation or 480-volt single phase or 3-phase operation. Request Bulletin 151.

Sweep Generator

A new Sweep Generator is now available from **Telonic Industries, Inc.,** Beech Grove, Ind., with twice the sweep width of

(Continued on page 152A)



At Bendix York, we have a number of immediate openings for Electronic Engineers and Physicists.

There are many worthwhile advantages awaiting the Professional Engineer who chooses to advance his career with us at Bendix York.

A white rose . . .

The white rose is a symbol at Bendix York . . . a symbol with two meanings. Both of vital importance to *your* future.

First, the white rose is the official flower of York, Pennsylvania. It is a symbol of the good life in our dynamic community, located in the heart of the scenic Pennsylvania Dutch region. It is a wholesome, happy area with excellent schools, delightful recreational opportunities and many cultural advantages. Here—away from high-pressure, high-cost, big-city living—you will enjoy the fuller, more rewarding life that you want for yourself and for your family.

Second, the white rose is a symbol of perfection . . . the perfection for which we strive at Bendix York—perfection in the engineering and scientific pioneering and development in missile electronics that is our principal objective.

We offer a small Division's assurance of individual recognition and advancement, and yet you have the security and employee benefits of a large corporation.

We would like to have the opportunity to tell you more about Bendix York. We invite you to contact us—by dropping us a post card, by giving us a call or, if you will, by sending us a brief resume. Address Professional Employment: Dept. P

SUPERVISOR
DATA RECORDING, INSTRUMENTATION, CONTROL SYSTEMS

Unusual opportunity exists with a well-known research organization for an electronics engineer with outstanding technical and administrative ability to supervise the activities of an expanding group of engineers engaged in research programs in the following areas:

Servomechanisms and Regulators
Analog Computation
Missile Guidance Systems
Industrial Process Control
Reactor Control Systems
Sensing Elements
Magnetic Recording

Our environment is midway between academic and industrial research and offers an excellent opportunity to develop research programs of greatest interest to you and your associates. Liberal benefits including four week vacation. Our location in a major midwestern city offers unlimited cultural and recreational opportunities.

Please send complete resume including salary requirement. All replies held in confidence.

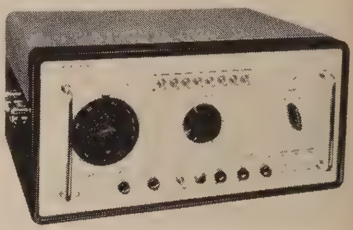
NEWS New Products

These manufacturers have invited PROCEEDINGS readers to write for literature and further technical information. Please mention your IRE affiliation.

(Continued from page 150A)

earlier models having the same range and power output. The new Model HD-1A, has a center-frequency range of 1 to 900 mc, and a sweep width that is adjustable up to 200 mc in the lower portion of the range.



The wide range is achieved by using two UHF swept oscillators, each with a range of approximately 400 to 900 mc. These are combined in a heterodyne circuit to produce a third signal that is tunable over a 1-to-400 mc range. The output of a single oscillator is used for the instrument's upper range, providing a continuous spectrum of center frequencies from 1 to 900 mc.

Sweep widths may be varied from 200 mc in the heterodyne portion of the center-frequency range. Over 400 mc, the sweep width is variable from 0.06 to 10% of the center frequency. Attenuators, detectors and other circuit elements are carefully designed for broadband performance so that the output is level across the entire swept frequency, even when set at the widest limit. The two oscillators are leveled by an automatic-gain-control circuit that continuously samples the swept output. Specifications for the HD-1A call for a flatness of less than ±5% at maximum sweep width.

The RF output of the instrument is a maximum of 0.75 volts, peak-to-peak, across the heterodyne range and 2.0 volts, peak-to-peak, in the high range. These voltages are adjustable by a turret attenuator mounted on the front panel of the instrument. Settings are provided for 0, 10, 20, 30, 40, and 50 db attenuations, plus a 0–10 db vernier.

By automatically blanking the return sweep, the Model HD-1A instrument provides a base line on the scope presentation. The horizontal sweep signal is 20 volts, peak-to-peak, with a repetition rate equal to line frequency, 50 to 60 cps.

Toggle switches on the face of the instrument introduce fixed "birdy" markers into the oscilloscope trace. Up to eight plug-in marker units may be used, each set at the factory to a particular frequency. In addition, harmonic plug-in markers are available that add birdies at 1 mc, 10 mc or other intervals.

High Temperature Precision Capacitors

A new line of precision film capacitors is now available in the −55°C to 125°C

ASTRONAUTS IN SEARCH OF A HELMSMAN

(it could be you!)

ELECTRONICS ENGINEERS: IT'S TIME TO SET YOUR COURSE WITH THE WORLD LEADER IN CONTINUOUS WAVE DOPPLER NAVIGATION SYSTEMS

When an astronaut is shot into space, a major factor in his survival will be the reliability of his guidance system. The "helmsmen" of space are electronics engineers. And Ryan Electronics needs dozens more of them now. Ryan is expediting a $20 million Navy contract, producing advanced navigational systems for many other major aircraft of our armed services and has pioneered C-W doppler techniques utilized in some of the nation's most advanced missiles.

The farther man departs from Earth, the more important becomes the reliability of the doppler principle, and the brighter the future of all who work with the leader in this field.

There are immediate openings with Ryan in two of Southern California's most progressive communities, San Diego and Torrance, noted for ideal climate, fine housing and outstanding educational facilities. If you've even considered making a change, for full particulars, send your resume or write for a brochure to Ryan Electronics, Department 4, 5650 Kearney Mesa Road, San Diego 11, California.

Mr. Engineer . . .

Retain your identity at

BECKMAN'S SYSTEMS DIVISION

in Orange County, California

Here's your chance to be a big fish in a small pond . . . not that our Systems Division is too small . . . it's just that we're not so large and over-organized that the individual and his efforts are submerged in a mass of humanity and a welter of paper work.

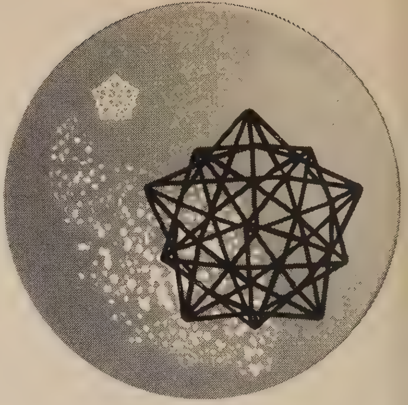
Our business is the design, development, and manufacture of proprietary electronic data processing and data acquisition system . . . research and development study projects pertaining to satellite programs . . . varied engineering design projects and other activities with both military and commercial significance.

There's ample elbow room for the non-organization man in any one of the following professional areas:

Logic Design **Systems Design**
Analog Design **Systems Engineering** **Digital Design**
Project Management **Project Engineering**
Electronic Design **Systems Evaluation and Modularization**
Field Engineering **Applications Engineering**

If you'd like to receive more information about us, we suggest you write to our Mr. J. W. Carlton enclosing a brief description of your background.

BECKMAN INSTRUMENTS, INC., SYSTEMS DIVISION
325 North Muller, Anaheim 5, California
(25 miles south of Los Angeles, near the Pacific Coast)



ENGINEERS
SCIENTISTS

FUTURISM in contemporary R&D

Radical departures from traditional forms of scientific investigation are the keynote of Republic Aviation's forward-looking programs in space exploration and upper atmosphere flight. In an environment that regards with skepticism the seeming validity of conventional conclusions, engineers and scientists seek below-the-surface solutions of problems... bypassing the superficial.

Expanding the scope and depth of present programs is Republic's recently completed $14 million Research and Development Center. Extensive facilities here are an invitation to professional men to realize the future by solving today's most perplexing problems.

• • • • • • • • • • • • • • • • • •

SENIOR LEVEL OPENINGS EXIST IN THESE IMPORTANT AREAS:

Navigation & Guidance Systems / Radar Systems / Information Theory / Radio Astronomy / Solid State & Thermionic Devices / Microwave Circuitry & Components / Countermeasures / Digital Computer Development / Radome & Antenna Design / Receiver & Transmitter Design / Miniaturization-Transistorization / Radiation & Propagation *(RF, IR, UV)* / Telemetry-SSB Technique

Please forward resumes to:
Mr. George R. Hickman
Technical Employment Manager,
Department 14D

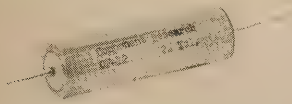
REPUBLIC AVIATION

Farmingdale
Long Island, New York

These manufacturers have invited PROCEEDINGS readers to write for literature and further technical information. Please mention your IRE affiliation.

(Continued from page 152A)

temperature range from **Component Research Co., Inc.,** 3019 So. Orange Drive, Los Angeles 16, Calif.



The capacitance change is less than 1% for the entire range. From 25 to 125°C the capacitance change is less than ±0.3% and zero ±30 ppm /°C temperature coefficient, which remains stable with repeated temperature cycling.

Insulation resistance is greater than 10^{13} ohms. Dielectric absorption is less than 0.0003 when measured with a charging voltage of 44 volts for 30 seconds.

The dissipation factor remains less than 0.0003 over the entire temperature range and a wide range of frequencies.

These CR PROCESS (pat. pend.) capacitors have a standard tolerance of 2% and are hermetically sealed in tubular and bathtub enclosures. Other tolerances ranging to 0.1% are available at all standard working voltages.

Special capacitors with less than ±0.3% total capacitance change from −80°C to 125°C can be supplied for unusually critical circuit applications.

These precision capacitors can be used in computers, timing circuits, servo systems, pulse filter networks and a variety of other applications.

Fire Retardant Casting Resin

Emerson & Cuming, Inc., Canton, Mass., announces a new fire retardant epoxy casting resin which may be cured at room temperature. The material has excellent adhesion to metals, plastics and ceramics.

Due to its low thermal coefficient of expansion and high heat stability, large embedments can be made. It is stable over a temperature range of −100 to +350° F. Stycast 1231 can be color coded to specification but normally is supplied in black.

(Continued on page 156A)

MAN OUT...

A fascinating project at Martin-Denver and one which offers to the truly creative engineer or scientist a personal esteem and professional recognition unequalled in today's opportunities. Please do consider being a part of this or other creative involvements at Martin-Denver and inquire of N. M. Pagan, Director of Technical and Scientific Staffing, (Dept. DD 9), The Martin Company, P. O. Box 179, Denver 1, Colorado.

MARTIN
DENVER DIVISION

MARTIN-DESIGNED CIRCULAR SPACE COMPUTERS ARE AVAILABLE **FREE** TO INTERESTED PERSONS BY WRITING TO THE SAME ADDRESS.

development engineers

The Brown Instrument Division of Honeywell has several openings for development engineers. Work involves responsibility for projects from drawing of the original requirement specifications, through the development and design phases, until finished drawings and specifications are released to the manufacturing department.

JR. & SR. ELECTRONICS ENGINEERS

Engineering grads with at least 1 year in electronics development work. Present or contemplated projects include development of high gain, low level d-c servo amplifiers; computing elements for industrial process control loops utilizing transistor and magnetic amplifier circuitry; sophisticated controllers for process control utilizing diode modulator techniques with a high audio frequency carrier; and high gain, wide band d-c amplifier development.

JR. & SR. ELECTRICAL ENGINEERS

BSEE's with at least 1 year of experience in the development of electrical measuring instruments such as potentiometer recorders with microvolt sensitivity, galvanometer indicating controllers, current actuated recorders, etc. Also involves development of many types of electrical transmitters and components such as strain gauges, galvanometers, slidewires, torque motors, and electro-mechanical transducers. Frequently the work on these instruments involves telemetering components, integrators, controllers and alarm devices.

ELECTRICAL PRIMARY MEASURING ELEMENTS ENGINEERS

BSEE's or Engineering Physics grads, with at least 3 years' experience, and interested in electrical output signal. Develop new products, investigate and correct unusual production and field troubles and keep in close contact with competitive developments.

If you are qualified and a U.S. citizen and interested in any of these openings, send information on your background and experience to C. R. Brandt, Employment Manager, Dept. 544,

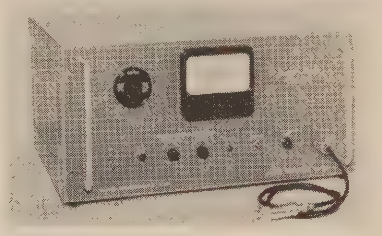
Thin sections of cured Stycast 1231 repeatedly introduced to a flame will, on each occasion, immediately extinguish.

Noise Source

The Mega-Node 3000, a noise-diode type calibrated noise source, providing low VSWR across a frequency range of 1 to 3000 mc, has been introduced by the **Kay Electric Co.**, Dept. PI, Maple Ave., Pine Brook, N. J., manufacturers of precision electronic test and measuring instruments.



Accurate noise-figure measurements require diode current to be known and generator impedance to be constant with frequency, since available noise power is a function of both. In the Mega-Node 3000, the generator impedance is held constant across the range by an impedance matching device that is simple in principle. Thus, the error introduced by the generator

CAREER OPPORTUNITIES
based on solid, long-term growth . . .

TOP EARNINGS
fully commensurate with experience . . .

CHALLENGING ASSIGNMENTS
made possible by project diversification.

STAVID has immediate openings available at all levels in research, design, development and field service engineering in the following areas:

- Sonar
- High-Power Modulation
- UHF & VHF Development
- Antennas
- Receivers & Transmitters
- Transistor Applications
- Microwave Development
- Digital Techniques
- Electro-Mechanical Packaging
- Pulse Circuit Techniques
- Telemetry
- I.F. & Video Circuitry
- Environmental Testing

STAVID's facilities in Plainfield, New Jersey, at the foothills of the Watchung Mountains, are near excellent schools, modern shopping facilities and ample housing accommodations. With New York City just 45 minutes away, and the New Jersey shore within one hour's drive, the Plainfield area provides an ideal environment for work, recreation and comfortable suburban living.

computer engineers

The acceptance by business and industry of the Philco 2000 All-Transistor Data Processing System has created a number of significant advancement opportunities in our organization both at our new headquarters in suburban Philadelphia and at various key locations in other parts of the nation. You are invited to call, write or visit us to discuss your future in our growth organization.

We have immediate assignments awaiting:

ENGINEERING PERSONNEL

Circuit Designers

Opportunities for experienced engineers at Senior, Project and Specialist levels to work in advanced electronic circuitry for digital computer core and drum memory elements.

Product Engineers

Qualified by experience in electronic computer test and debugging for final product evaluation and acceptance of large-scale, high speed all-transistor digital computer system.

Programmers

Mathematicians and Physicists experienced in the elements of sophisticated automatic programming systems to develop efficient, logical programs for control computers.

SALES & MARKETING MEN

Sales Representatives

Experienced in actual sales, installation and servicing of engineering and business data processing systems in major industrial concerns.

Systems Analysts

Degree required, with 5 years' experience in the analysis of Engineering, Scientific, business data processing and military problems.

Programmers

Experienced computer programmers in any of the following fields: Sophisticated Automatic programming systems • Engineering & Scientific Problems • Business, Industrial & Financial Applications • Military Tactical & Logistical Applications.

Customer Service Engineers

Experienced computer engineers for local and out-of-State assignments in major metropolitan areas to install, start up and maintain large-scale, high speed digital computer systems. Advanced training on all-transistor equipment furnished prior to assignment. Also openings for instructors and technical writers with experience in the computer field.

IF YOU QUALIFY, CALL OR WRITE TODAY

Cambridge 39, Massachusetts
UNiversity 4-6900, Ext. 3544

● Graduate courses may be taken for credit while earning full pay ● U.S. Citizenship required

(Continued from page 156A)

VSWR (impedance variation) is minimized.

Rapid, accurate measurement of noise-figure can be accomplished without calculation of the effective bandwidth. Variable noise-power range and low VSWR permits accurate noise-figure measurements. Calibration charts and slide rule are not required to determine noise-figure.

A coaxial-type, tungsten-filament noise diode is employed as a temperature-limited noise-generator. Plate voltage is regulated and diode plate current, which is proportional to noise power output, is adjustable by a front panel control. Current is indicated on the panel meter, calibrated in noise-figure. To prolong the life of the noise diode, an automatic cutoff is incorporated to limit the time of operation at high currents.

The panel meter reads noise-figure directly up to 20 db for a 3 db Y-factor. Maximum VSWR is 1.15 from 1 to 250 mc; 1.25 from 250 to 2000 mc; 1.4 from 2000 to 3000 mc. Noise-figure accuracy is ±0.25 db from 1 to 250 mc. At the higher frequencies, the noise-figure error (db) is a function of the generator VSWR, but does not exceed SWR (db)/2.

Maximum VSWR indicated occurs at frequencies which represent less than 20% of the total frequency range. The VSWR over most of this range is much lower than the maximums specified.

Specifications: Frequency Range, 1 mc to 3000 mc; Output Impedance is Nominal 50 ohms (type-N connector); Noise Figure Range, is 0 to 20 db; Meter Calibration, Logarithmic in db noise-figure and linear in dc ma; Noise Diode, Bendix Type TT-1. Power Supply, Input approximately 200 watts, 117-v (±10%), 60-cps (Available for 50-cps operation on special order). B^+ electronically regulated. Dimensions, $9\frac{3}{4}'' \times 19\frac{1}{2}'' \times 15\frac{1}{2}''$; Weight: 44 lbs.

Transistorized Frequency Changers

ERA Pacific, Inc., 1760 Stanford St., Santa Monica, Calif., announces new additions to its line of transistorized frequency changers. These units convert one input frequency to a second frequency at power levels and eliminate the disadvantages inherent in vacuum tube or mechanical equivalents. The new units are designed for powering all types of AC equipment, gyro and servomechanisms, magnetic amplifiers and are intended for laboratory and industrial applications.

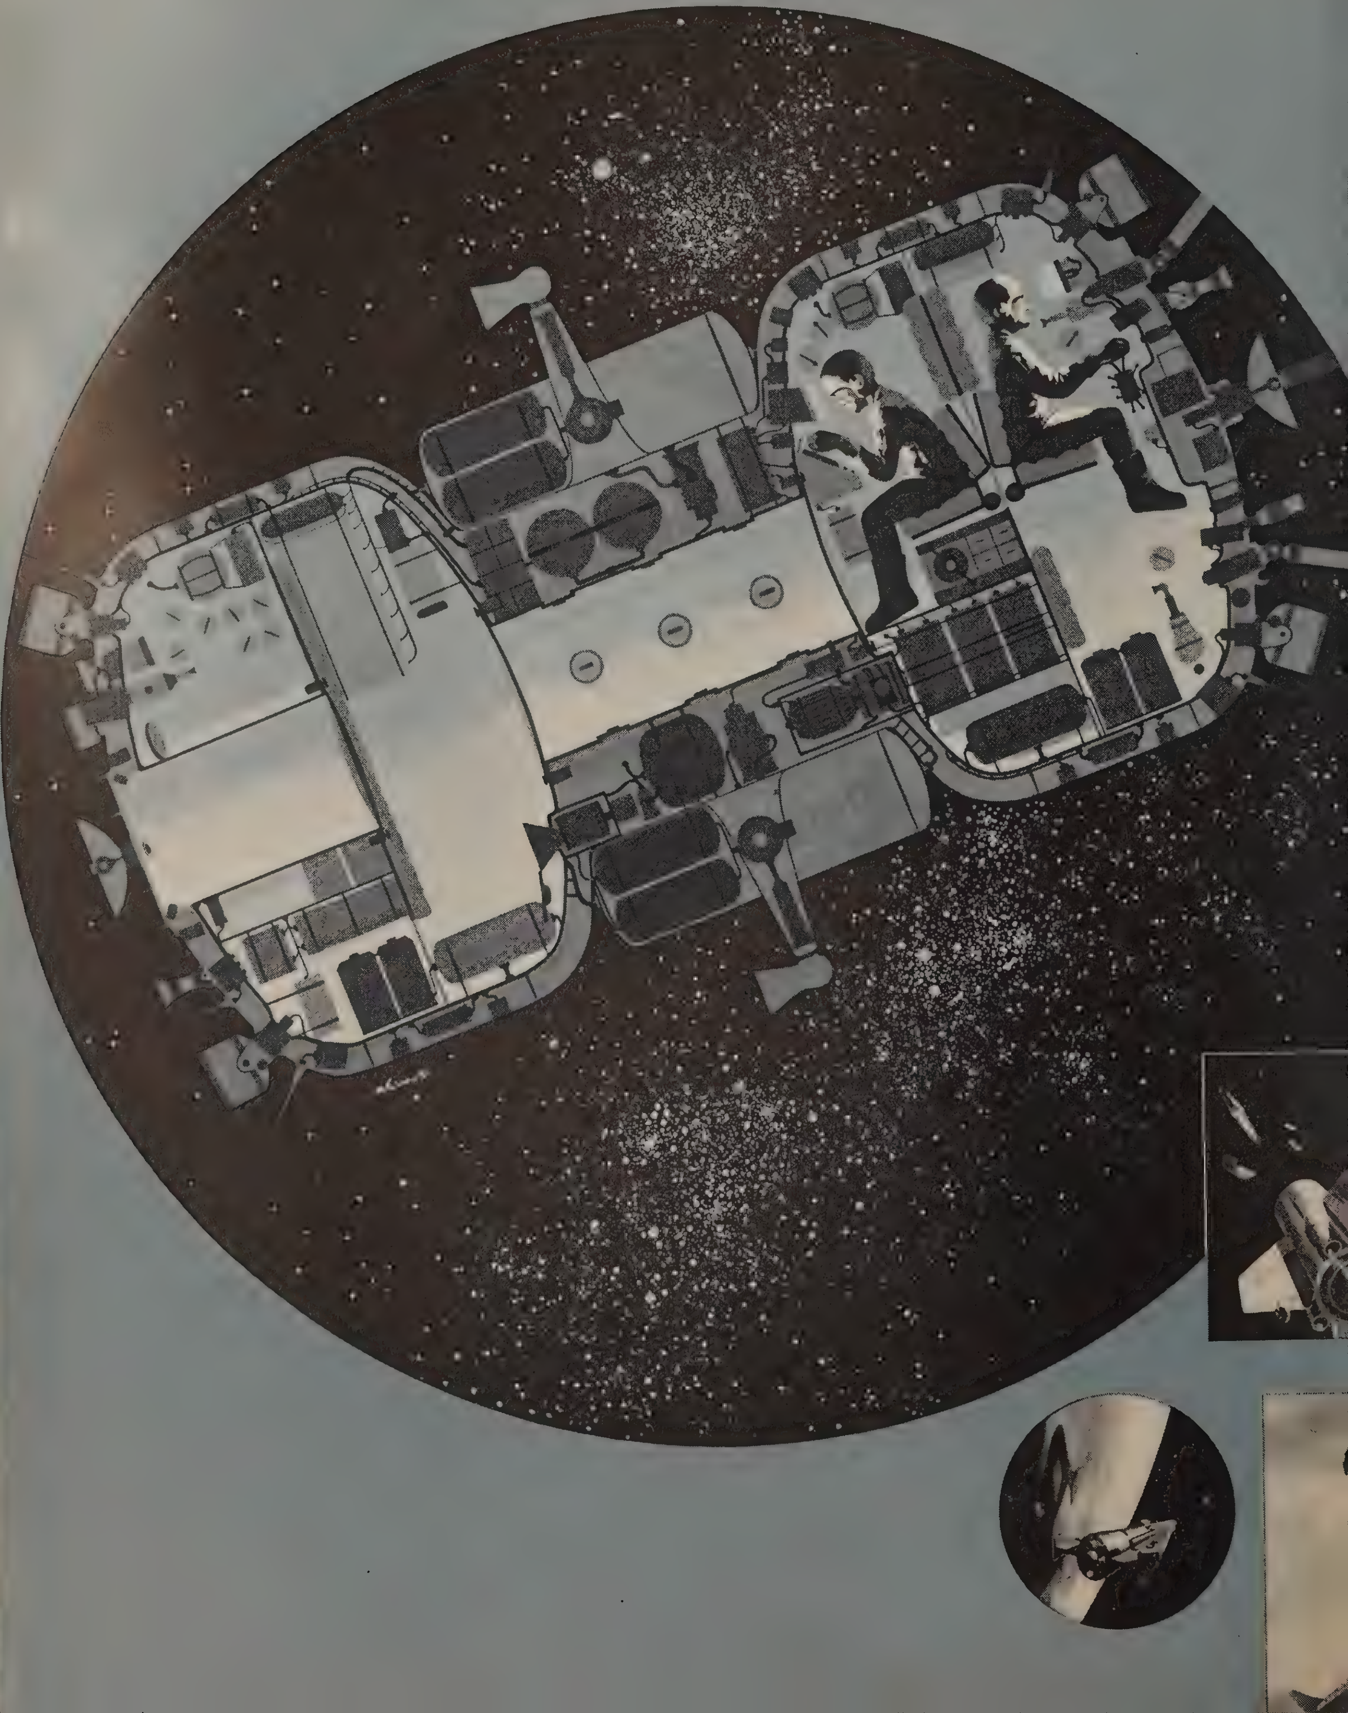
EXPANDING THE FRONTIERS OF SPACE TECHNOLOGY



THE
STROTUG

Tugboat for Space: Spaceborne scientific laboratories and platforms for further exploration into space are an accepted concept based on established engineering techniques. Components would be fired as individual units into space, on precalculated orbits, and there assembled. To solve the major problems of how men are to live and work in space during the assembly process, Lockheed has prepared a detailed engineering design of an astrotug - a manned vehicle housing a crew of two or three. Missile-launched, the astrotug will be capable of supporting its crew for a number of days in an environment of suitable atmosphere, artificial gravity, and with provisions for exercise, relaxation, bathing facilities, medical care, illumination and adequate food and water.

The Lockheed astrotug is a completely independent working vehicle. Personnel need not leave it in space suits in order to work on the project of assembling the space station components. As shown in the diagram, the tug consists of two double-walled pressure vessels approximately 20 feet long overall and 9 feet in inside diameter. Swivelling rocket nozzles are arranged for maneuvering. On the forward end, extending out are four mechanical manipulator arms with interchangeable "hands" for such specialized functions as gripping, welding, hammering, cutting, running screws, etc. "Hands" can be changed by remote control from inside. Viewing ports provide uninterrupted observation. Radar antennas, searchlights, and other equipment necessary to the tug's work are mounted externally. Main controls and instruments including radar, radio, infrared, computers and navigation consoles are duplicated in each of the two major compartments as a safety measure.

Men working in single units afloat in space suits would have little applicable force and could work for very limited periods of time. With the Lockheed astrotug, personnel could carry on the work in relative safety and comfort with maximum efficiency. A special reentry vehicle, separate from the astrotug, has been conceived for ferrying to and from earth. Tugs themselves would remain floating in orbit indefinitely, being reprovisioned and refurbished as fresh crews arrive in relief.

Space vehicle development is typical of Lockheed Missiles and Space Division's broad diversification. The Division possesses complete capability in more than 40 areas of science and technology – from concept to operation. Its programs provide a fascinating challenge to creative engineers and scientists. They include: celestial mechanics; computer research and development; electromagnetic wave propagation and radiation; electronics; the flight sciences; human engineering; magnetohydrodynamics; man in space; materials and processes; applied mathematics; oceanography; operations research and analysis; ionic, nuclear and plasma propulsion and exotic fuels; sonics; space communications; space medicine; space navigation; and space physics.

Engineers and Scientists: Such programs reach far into the future and deal with unknown and stimulating environments. It is a rewarding future with a company that has an outstanding record of progress and achievement. If you are experienced in any of the above areas, or in related work, we invite your inquiry. Please write: Research and Development Staff, Dept. D-33, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship or existing Department of Defense clearance required.

RESEARCH AND DEVELOPMENT ENGINEERS

Interested in—DIRECT CONVERSION OF HEAT INTO ELECTRICITY

●

For the past several years THERMO ELECTRON ENGINEERING CORPORATION has been engaged in the research and development of thermionic converters and magnetohydrodynamic systems. Because of greatly increased activity on these advanced projects, we are pleased to announce the following immediate openings:

MECHANICAL OR ELECTRICAL ENGINEER—PROJECT LEADER LEVEL

To direct and coordinate research projects. Broad experience in vacuum tube technology necessary. Must have administrative or supervisory experience. Experience with metal or ceramic vacuum tubes highly desirable. M.S. degree preferred.

MECHANICAL ENGINEER, M.S. LEVEL OR EQUIVALENT

To design advanced systems utilizing direct conversion schemes. Must have analytical experience in heat transfer and strength of materials. Experience in high temperature applications desirable. Work includes preliminary design through to final prototype analysis.

ELECTRICAL ENGINEER

To design, execute and interpret experiments in vacuum tubes. Ability to design and build electronic circuits for measuring very small currents necessary. Broad experience in vacuum tube technology and preference for experimental work highly desirable.

PHYSICS MAJOR, M.S. LEVEL OR EQUIVALENT

To perform theoretical analysis and associated experiments in electron and ion dynamics. Broad experience in field of vacuum technology and familiarity with metallurgy and materials in vacuum tube technology highly desirable. Capable of assuming technical direction and responsibility for challenging projects.

●

In each case, salary is commensurate with education and experience. To arrange for an interview please write Edward Browne.

THERMO ELECTRON

ENGINEERING CORPORATION

171 HARVEY STREET • CAMBRIDGE, MASSACHUSETTS

Leaders and Pioneers in Direct Energy Conversion

ENGINEER
or
PHYSICIST

An unusual opportunity to do development work on a new approach to the manufacture of Capacitors is available to the man with the appropriate degree and three to five years experience in the development of electronic devices.

Competent technical assistance will be provided and the resources of an organization of substantial reputation in the field of electronic components are assured.

Salary commensurate with experience and an excellent employee benefit program will afford security for your family and permit residence in a community of fine homes and educational facilities.

Direct inquiries to:

UNION CARBIDE

SCIENTISTS . . .

ENGLISH ELECTRIC AVIATION LIMITED

(Guided Weapons Division)

LUTON BEDS.

LEADERS IN NEW PROJECTS AND ADVANCED STUDIES

Applications are invited from scientists for positions in which they will lead groups conducting feasibility studies in Advanced Weapons Systems and Satellite Projects.

Candidates should preferably have had experience of Research or Development work in related fields, but previous work on Guided Weapons, Aeronautics or Armaments is in no way essential. Degree or equivalent qualifications in either Physics, Mathematics, Electrical or Aeronautical Engineering is necessary.

For these posts (equivalent approximately to Principal Scientific Officer) the Company will give assistance with housing and removal expenses.

Please write to Dr. D. A. Layne, c/o Dept. C.P.S. Marconi House, 336/7, Strand, London, W.C.2, England, quoting reference 1395D.

These manufacturers have invited PROCEEDINGS readers to write for literature and further technical information. Please mention your IRE affiliation.

(Continued from page 158A)

Three new models are available—the Model FC 6415 which converts an input frequency of 60 to 400 cps at a 150va power rating, the Model FC 6410 which converts a 60-cycle input to a 400-cycle output at 100 va, and the Model FC 645 at 50va. These models provide a regulated output frequency compensated against both input and load variations.

The new models achieve frequency conversion by means of special circuitry which converts the input frequency to dc by means of silicon rectifiers. This dc, in turn, is converted to the desired output frequency by means of stabilized transistor keyers. This design approach permits desirable achievements, such as instant starting, small size, light weight, zero maintenance, negligible radio interference and high shock vibration resistance characteristics.

Contact-Making Wattmeter

A new kind of ac-dc contact-making wattmeter, capable of both indicating and controlling power in the lower milliwatt range, is announced by **Assembly Products Inc.**, Chesterland, Ohio.

(Continued on page 165A)

gp

Now that you're back . . .

. . . after attending the IRE Convention in New York, give serious thought as to where you're going.

If the position you're holding is just a job, without creative satisfaction, take the big step. Jot down a resume; send it to GUILFORD. All FEES PAID.

ACF ELECTRONICS DIVISION

ELECTRO-PHYSICS LABORATORIES

is accelerating its progress in challenging areas such as Project TEPEE. Responsible assignments in furthering the state-of-the-art of Ionospheric Physics, combining competitive salaries and unusual growth potential, are offered to men who can contribute. Our immediate needs are:

SCIENTISTS & ENGINEERS

for

research programs

in

IONOSPHERIC PROPAGATION
& HF COMMUNICATIONS

senior ionospheric physicists

Ph.D. preferred, with several years' experience in Ionospheric Phenomena studies. Familiar with latest knowledge of upper atmosphere physics and of programs using missiles and satellites for Ionospheric studies. Persons with supervisory capabilities will have the opportunity to assume leadership of HF projects already underway in the first phases of a substantial experimental program.

senior development engineers

Senior Scientists and Senior Engineers with current experience in state-of-the-art techniques in the design and development of HF receivers and transmitters. Specific experience desired on High-powered HF linear circuits. Work is evenly divided between engineering and development, including breadboarding.

senior electronics engineers

R & D Operations Liaison. Must have demonstrated technical ability to direct the incorporation of modern ideas into field equipment: to actively participate in the equipment transition from prototype to operational status. These are senior appointments as liaison between our R & D Equipment Development Laboratory and Field Operations. Degree in E.E. and the ability to communicate effectively are required.

junior electronics engineers

To assist Senior Engineers and Scientists in the development of HF communications and Data Process equipment. Should have formal electronics schooling and two years' experience in circuit design, checkout or analysis of HF Communications, Radar Pulse, Analog/Digital or Data Recovery equipment. Construction of prototypes of new and interesting equipment of these and design of individual components of communications and data processing systems will comprise the major efforts of selected applicants.

The Electro-Physics Laboratories are located in the suburban Washington, D.C. area, where post-graduate study is available in several nearby universities. Housing is plentiful in attractive, well-established neighborhoods. Our relocation allowance is liberal. Inquiries are held in complete confidence. A prompt reply will follow the receipt of your resume by:

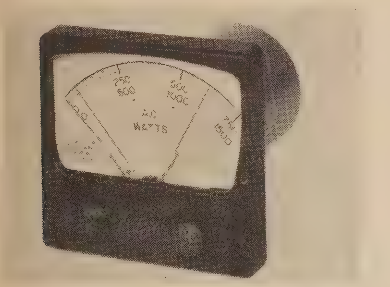
(Continued from page 163A)

Although primarily intended for measuring power, the unit also is available in modified form as a true RMS voltmeter or ammeter, or as a varimeter. The instrument can monitor the product of as many as four different variables.

Main elements of the instrument are a locking contact meter-relay and a magnetic circuit built around a Hall effect solid state device. They come in a panel-mounting package with a 4½-inch meter and a barrel less than 5 inches long.



Greatest standard full scale sensitivity at present is 500 milliwatts, either ac or dc, but with modifications dc ranges as sensitive as 100 milliwatts are available. The instrument can be built to operate on any ac frequency up to 1000 cps. Either ac or dc must be specified—they cannot be measured interchangeably by a single instrument.

Power measurement is simplified by eliminating the standard dynamometer movement of wattmeters. This is possible because the Hall device puts out a voltage that is proportional to the power in a load circuit. The output voltage is fed to a standard D'Arsonval movement that is directly calibrated for power measurement.

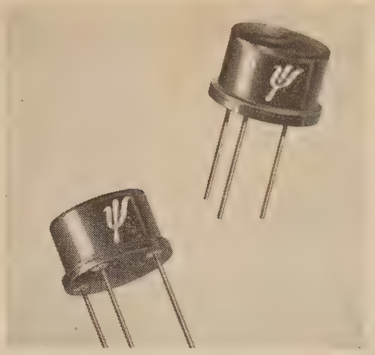
As with standard API locking coil meter-relays, control action begins whenever the signal pointer reaches a limit set by either a high or low adjustable pointer. Circuits are then closed that actuate load relays and other control components.

The new wattmeter is available with any of the standard API circuits used with locking contact meter-relays to provide a variety of control patterns. One of the more obvious applications is controlling motor load, since power is a more reliable measurement factor than the current alone that is frequently used.

Where remote indication or control adjustment is desired, the meter-relay and the associated circuitry are furnished in two packages for separate mounting.

Silicon Mesa Power Transistor

Pacific Semiconductors, Inc., 10451 W. Jefferson Blvd., Culver City, Calif., announces very high frequency silicon mesa power transistors capable of delivering one watt power output at 70 mc with a 28 volt collector voltage.



The two new types, designated as 2N1505 and 2N1506, are characterized by 3 watt collector dissipation, 40 volt collector to emitter rating, and low collector capacitance. The units are suited for VHF power application in communications and telemetry equipment where severe environmental conditions are encountered.

Type 2N1505 operates as an oscillator at 70 mc with a power output in excess of 1 watt at an efficiency of 45%.

Type 2N1506 has a typical power gain of 12 db at 70 mc with a useful power output of 1.0 watts. At 200 mc the 2N1506 has a power output of 300 milliwatts.

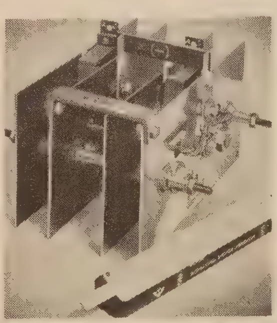
Delivery is currently being made on both new types. The 2N1505 is priced at $39.50 up to 99 pieces at $29.60 up to 1000 pieces. The 2N1506 is $49.50 and $37.00 respectively.

The new types supplement the present PSI line consisting of high frequency, high power, high voltage types 2N1335–1341, the multipurpose high speed switches 2N1409–1410 and medium power high speed types 2N696/697.

Detailed technical data on the 2N1505 and 2N1506 transistors is available from the factory.

High Power Silicon Rectifier Stack

Pre-engineered high power silicon rectifier stacks incorporating built-in paralleling reactors to insure equal current distribution through parallel circuit branches are now available from **International Rectifier Corp.,** 1521 E. Grand Ave., El Segundo, Calif. The units feature ratings up to 750 amperes, with from 50 to 600 volts peak reverse voltage ratings.



A standard "building block" is a 2-1-2-D "doubler" module with integral parallel-

You'll find new opportunity
new reward
in the new look at Link

It's even more exciting – and certainly more real – than looking-glass land and nearer to now than the closest mirror.

Right now, things are really humming at the Link Division of General Precision, Inc. Link is one company which has accepted the challenge of the years ahead with eager enthusiasm. In fact, projects now under way at Link are among the most advanced in the nation.

At Link, engineers are busily engaged with research and development on "Dialog" systems, sub-systems and components. Another example of Link/ability, "Dialog" systems planning combines digital computation with analog measuring. It offers the best of both—in compatible form—to meet the most exacting control, design, analysis and scheduling specifications.

But let's be honest. Without top caliber engineers we can't really do anything. That's why engineers coming to Link today have Opportunity with a capital "O".

If you are an electronics engineer who thinks big—who has original ideas and follow-through to make them click, why not write today, or send your résumé—in complete confidence—to:

Mr. C. P. Darrah

ing reactor, and four 70 ampere rated silicon junction rectifiers mounted on copper cooling fins. Two of these modules may be mounted to from a single phase bridge (as shown in photo) rated up to 550 amperes rectified dc output (when operating within recommended temperature and cooling limits).

Three of these basic modules will form a 3-phase bridge rated to 750 amperes. Other configurations include "Scott 4-phase bridges," and 6-phase bridges in both series and parallel connections and proportional ratings.

For detailed data on this new high power silicon stack line, request Bulletin SR-336.

Piore and Palmer Appointed By IBM

A separation of the corporate staff research and engineering function of **International Business Machines Corporation** into two functions was announced today by President Thomas J. Watson, Jr.

Dr. Emanuel R. Piore, IBM director of research, will now report directly to A. L Williams, IBM executive vice president. Dr. Piore was also named chairman of the company's Research and Development Board. The board serves to assure the most effective direction and·use of IBM's total technical resources.

Ralph L. Palmer, IBM director of engineering, will also now report to Williams and will continue to exercise staff supervision of the company's engineering activities.

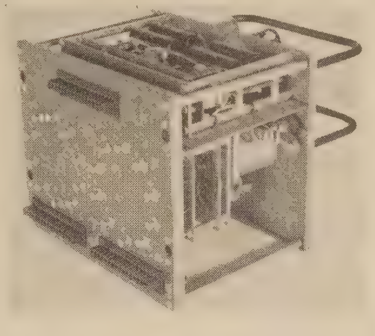
Research and engineering were previously combined under W. W. McDowell, formerly vice president for research and engineering, who was appointed resident vice president for IBM's operations in Endicott, N. Y.

Dr. Piore joined IBM in 1956. He previously was vice president in change of research for the Avco Manufacturing Co. From 1946 to 1955, Dr. Piore was with the Office of Naval Research, becoming ONR's chief scientist. He is a member of President Eisenhower's Science Advisory Committee.

Palmer, an electrical engineering graduate of Union College, Schenectady, N. Y., joined IBM in 1932 at Endicott, N. Y. He subsequently served in various managerial positions in the company's engineering and research operations.

Multiple Circuit Switch

A new, simplified method of switching multiple circuits in television broadcasting operations has been announced by **Telecontrol Corp.**, 1418 W. 166th St., Gardena, Calif.



The new "building block" switching systems design permits simultaneous multiple circuit switching, with a reduced investment in switching equipment. The basic switching modules can be applied to all television switching operations, including studio, master control and distribution switching systems.

Key to the switching module concept is a new type of multiple circuit rotary stepping switch. The remotely controlled switch is adaptable to various methods of control within television broadcast installations of all sizes.

Telecontrol switching modules have a number of inherent advantages over video relays of transistor-diode switching assemblies, according to the firm. Switching is accomplished within a one-inch radius, designed for video switching with extremely low capacitance. This results in low cross-talk and flat frequency response, even when a large number of modules are employed.

The stepping switch can handle simultaneous switching of various combinations of video, sync, audio, control and tally circuits within the same module. It also utilizes a wide range of control flexibility in remote positioning, including pulse control, rotary selector control and pushbutton selection.

Another advantage of the Telecontrol switching concept is that it permits high-speed off-air switching, with rotation to the extreme position in the order of 0.05 seconds.

Distribution switching modules (Series VSA, VSB, VSC) are designed for video distribution exchange systems, house monitoring systems and other applications where off-air pre-selection is permitted.

The distribution modules offer a number of advantages over conventional patching methods, which require a large number of circuit connections, the services of a skilled operator and time for set-up. Remote control switching with the Telecontrol modules sharply reduces the number of required circuit feeds, releases the op-

(Continued on page 168A)

Engineers:
There's new
opportunity at Link

Among the opportunities at Link, Binghamton, are:

DIGITAL COMPUTER ENGINEERS

Several senior staff engineer and senior electronic engineer opportunities have been created by the formation of the new Digital Systems Development Department.

Assignments will include the evaluation of digital systems, covering the responsibility for development project design groups. Important technical contributions will include development work on "NOR" Logic, Direct-Coupled Transistorized Logic, and other techniques for future digital projects.

Requirements include minimum BSEE or BS (Physics) with experience in digital systems design and computer check-out, and/or transistor circuit design.

SENIOR STAFF ENGINEER

To prepare, coordinate and evaluate proposals for contract sponsorship of development programs; assist laboratory manager in evaluating ideas for company sponsored development; investigate new product areas for marketability, investment and present Link capability to government and industrial concerns.

Minimum BSEE with advanced work in communications. MSEE (communications) preferred.

Experience must include 10-12 years in electronic system and hardware design and a broad background in several related areas including: early product design experience in military electronics; design of custom electronic products for commercial aviation.

If you are an electronics engineer with an eye towards a brighter, more rewarding future, why not write or submit your resume—in complete confidence—to Mr. C. P. Darrah.

Are You a Systems-oriented Engineer?

Simple and clear-cut, Alpha's internal organization is aligned to provide systems coordination by means of vertical integration of management, engineering, and administration of each project within the division to which the project is assigned. Each project division is under a Vice President and Project Executive who is organizationally a part of the central management of Alpha. Functionally, the Project Director, together with the project's own engineering, operations, materiel, contract administration, and business development personnel, deals directly with the customer and has complete authority, responsibility, and accountability for the timely execution of the project.

Does this team-oriented attitude that engenders effective interfacing relationships and intra-team communications appeal to you? Do you have systems-oriented technical talent with the specialized capabilities needed to determine system parameters; integrate a complex of equipments; direct subsystems suppliers? Write:

erator for other assignments and reduces total setup time to seconds.

Ten or 20 inputs are standard for all distribution and program switching modules. For switching NTSC color video and for large video distribution exchanges, special compensated switching modules are available with built-in equalized impedance and phase shift compensation.

Modular In-Line Switch

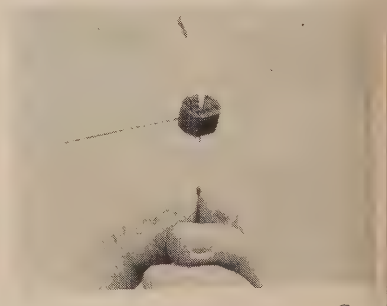
The Digitran Co., 660 So. Arroyo Parkway, Pasadena, Calif., announces a new panel switch concept (the new 7300 Series). The Digiswitch replaces ten-position, or octal, switch units of the rotary type. Panel space requirements are reduced so that designers can mount four times as many Digiswitches in the normal space required for rotary switch elements.

The switch is finger controlled and provides for ten-position, single-pole and double-pole, binary coded decimal with variations, and octal 0, 1, 2, 4 coded outputs. Internal lighting of the readout and color coding of the switch tabs are also available.

The in-line readout is said to reduce reading errors and simplify switch setting. The unit finds its applications in automation, automatic control systems, computer designs and other systems which require the setting of numerical constants or coefficients.

The Digiswitch is designed in switch modules which permit ganging in any desired number. For descriptive data sheet No. 7300, write to the firm.

Current Sampling Transformer



Valor Instruments, Inc., 13214 Crenshaw Blvd., Gardena, Calif., has introduced the IST series of seven pulse cur-

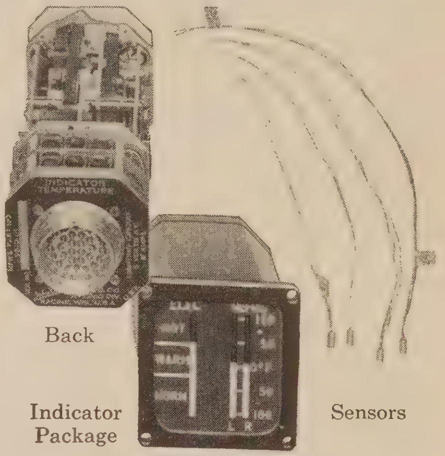
How do you take the temperature of an electronic system?

Use ONE Compact, Accurate, Lightweight, Completely Transistorized Oster-Developed Temperature Indicating System. Replaces 6 Indicating Systems.

The device illustrated senses and displays the highest of 4 temperature sensor signals on the Convair B-58 supersonic bomber. It also reads out the temperature of the plane's 2 refrigeration systems. However, the unit can monitor temperature of any military or commercial electronic system. Special versions can be furnished to monitor any analog voltage signal.



Back

Indicator Package

Front

Sensors

Oster®

Entire unit (component parts illustrated) has an accuracy of 1½%, weighs only 3.85 lbs. max., requires only 2⅜″ panel space, and does the work of 6 indicating systems. Component parts consist of 4 sensors, a computer package with 6 channels, and a hermetically sealed indicator package.

The unit is typical of Oster designed equipment.

Periodic Permanent Magnet Oscillator

Huggins again demonstrates leadership in TWT production with a Backward Wave Oscillator focused in a periodic permanent magnet structure. This development opens a wide range of new uses for the BWO. With no cooling required, all need for auxiliary power is completely eliminated. Savings in size and weight are impressive. An 11½″ x 2½″ capsule, weighing 3.5 pounds replaces a solenoid and power supply weighing approximately 50 pounds.

HO 22 SPECIFICATIONS

Frequency	Min. Power Output
8.5 to 12.0 KMC	10 dbm
8.2 to 12.4 KMC	5 dbm

Tuning voltage range is 400 to 1800 volts.

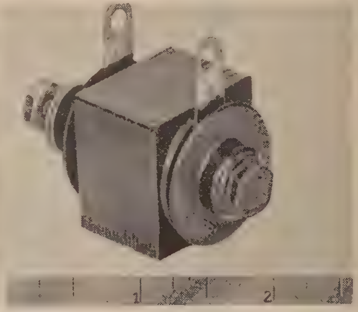
rent sampling transformers which deliver synchronizing voltage pulses for use with radar transmitters or other devices which develop high pulse currents. The voltage pulses have the same shape as the high current pulses. No resistance is added to the circuit because the transformer is not connected to the current carrying the conductor; voltage pulses are developed by passing the conductor through the hole in the transformer. This new approach eliminates the resistive networks used in conventional methods.

Specifications: Size $\frac{9}{16} \times \frac{1}{2} \times \frac{3}{8}''$; Weight $\frac{1}{8}$ ounce; Ratio 20:1 to 150:1; Pulse Widths 0.4 to 3.0 μsec at 50 volts; Inductance 0.12 to 6.0 MH; Optimum Load 50 to 500 ohms; Meets MIL T27A.

Price: 1–4 units $7.70 each; $4.60 each for 100. Delivery: From stock typically; two weeks maximum.

Silicon Rectifiers Surge Protector

Type SP Surge Protectors manufactured by **Electric Products Division, Dept. 502P, Vickers Incorporated,** 1815 Locust St., St. Louis 3, Missouri, protect silicon power rectifiers from breakdown due to transient high voltage.



Non-linear resistance, decreasing with increase in voltage, plus built-in capacitance, absorbs intermittent surge energy up to 3000 watts, limiting voltage to safe value for silicon rectifier. Consumes less than 5 watts under steady-state conditions.

Nine standard types cover the range of 50 to 600 volts normal PIV rating. Field tested for more than a year; laboratory surge tested for more than 5 million cycles.

FREQUENCY METER
MODEL 7175

Measure 10cps to 110Mc with one compact meter

Comprehensive range for only $1895. Never before has so broad a range been offered for so low a price—a combination made possible by closely integrating a simple heterodyne converter with a top-notch 10Mc counter. Frequencies up to 10Mc are measured by direct counting. To measure frequencies above 10Mc, the operator simply rotates reference frequency selector until panel meter shows strong deflection, then reads counter indication. Measurements take less than a minute to make. Accuracy far exceeds FCC requirements over communications range. Possible error is .00004% or less from 1Mc to 110Mc.

Write for technical bulletin on Model 7175.

Min Rac 17

miniature rack & panel connectors with POKE HOME® contacts

Solve space, weight and size problems with AMPHENOL's new Min Rac 17 connectors, true miniatures with the "Big Plus" advantage of Poke Home contacts! Min Rac 17's are rack & panel connectors ideally suited for today's compact chassis designs, connectors half the size and weight of standards, delivering full size efficiency. And with the patented Poke Home contact concept (U.S. Pat. 2,419,018), Min Rac 17's are easily, reliably assembled—contacts are crimped or soldered outside the connector body, then "poked home" for assembly.

Min Rac 17's are available in 9, 15, 25, 37 and 50 contacts in rack & panel, cable-to-chassis and cable-to-cable designs. Contacts are gold plated. Shells may be ordered with clear chromate or gold iridite finish.

These remarkable connectors are available now—write for full catalog!

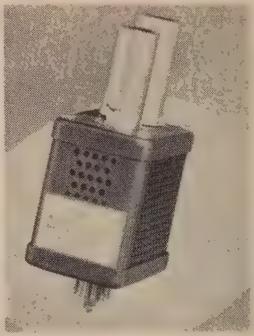
Peaked Amplifier

CES Electronic Products, Inc., P.O. Box 7504, San Diego 7, Calif., has announced development and production of a new peaked amplifier in the 15 to 2000 cps range.



The new unit, Model 107-B, is a three stage direct-coupled amplifier with a CES Twin-T Filter in the negative feedback loop. The filter gives at least 50 db insertion loss at its balance frequency and the normal feedback is at least 70 db. This retains 20 db feedback for stabilization at the peaked frequency and results in a very sharp, deep-shouldered response curve. The performance of the amplifier is independent of the driving point impedance and can be terminated in any high impedance load. Q's of 100 are attainable with excellent stability.

According to the company, the amplifier is available in standard models for frequencies from 15 to 2000 cps. Special models with frequencies as low as 0.01 cps can be supplied on special order.

For additional information, write to the firm.

Rotary Solenoids And Stepping Motors

A new application guide to Ledex rotary solenoids, selectors and Syncramental stepping motors has just been issued by **G. H. Leland, Inc.,** 123 Webster St., Dayton, Ohio.

This eight-page bulletin (No. A-1259)—illustrated with line drawings, charts, photographs and circuit diagrams—contains specific physical, performance and environmental data on more than 250 different models available for immediate delivery. It also supplies information on how to use this data to select the proper rotary solenoid, selector or Syncramental stepping motor for any application.

Only half the size of ordinary units Leland's highly efficient Ledex rotary solenoid is capable of developing twice a much power as these ordinary solenoids.

Its stepping and selector switch—

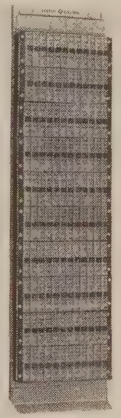
(Contnued from page 174A)

which can be manufactured in hermetically-sealed containers—has replaced the use of numerous ordinary relays in many applications where space and weight present a problem. Ledex stepping and selector switches require only one-fifth the space formerly taken up by ordinary relays.

A versatile, high-precision, bi-directional stepping motor, the Ledex Syncramental motor develops at least three times greater torque than comparable devices can provide. During its design life of 2,000,000 steps in each direction, the probability of its missing a step is only 1 in 1,000,000.

600-Channel Transistorized Multiplex Carrier



General Electric Co., Communication Products Dept., Lynchburg, Va., announced today that it has developed a transistorized multiplex-carrier system capable of handling up to 600 voice frequency channels on a single radio beam.

Fully transistorized, the new General Electric single sideband suppressed carrier system has toll quality capable of meeting international and domestic long-distance standards.

In the new multiplex-carrier, reliability is enhanced by the use of a technique which utilizes a standby component for each component in the common equipment, such as amplifiers and master oscillators. Upon failure of an individual part, the parallel component keeps operating, with no switching delay to seriously affect data transmission."

Also achieved is a substantial reduction in power drain. Typical equipment currently available requires thousands of watts for a system utilizing 240 channels. This design takes less than 700 watts for the corresponding capacity.

Despite the increase in capacity which makes 600 channels available, this unit is one-third the size of conventional tubed equipment. G-E's design makes possible 120 channels in an eight-foot space where only 24 channels previously could be accommodated.

Computer Grade Electrolytics

Spincasting

A significant contribution to Antenna Technology by D. S. KENNEDY & CO.

Kennedy engineers and scientists have successfully applied a simple scientific principle to the manufacture of large antennas. The application of this principle that "the surface of a liquid when spun about a vertical axis assumes a paraboloidal shape" will result in several important benefits.

First, surface accuracy of antennas should improve by more than an order of ten. This is possible even though the surface to which the liquid is spuncast is irregular, because such irregularities in the container in no way affect the smooth accuracy of the surface of the liquid.

This means substantial savings in time and money in the manufacture of antenna dishes of this accuracy, as well as antennas of greater efficiency.

There is no theoretical limit to the size of dish Kennedy may be able to Spincast. Dishes up to 10 feet in diameter are already in production and Kennedy is ready to receive inquiries as to the application of this technique to your problems. For complete information write, wire or call collect — EVergreen 3-1200.

SAVE VALUABLE COMMUNICATION DOLLARS
with RIXON'S LOW NOISE PREAMPLIFIERS

Much effort has been made and is being expended to reduce "noise" in receiving systems because of the potential dollar savings resulting from improved receiver performance. Even if the "noise" does not materially effect the performance of the receiving system, if there is a long transmission line between the antenna and the receiver, the signal power is reduced by the transmission loss in the line.

The Rixon 400-500 mc preamplifier, shown here, with noise figures in the 4 to 5 db-range, makes a major improvement when placed in front of a 10 to 12-db commercial receiver. It's the same as a four time increase in transmitter power.

Other Rixon Preamplifier Models are available on short notice and are easily adapted at the factory to cover any band in the 10-500 mc frequency range.

SPECIFICATIONS

AP-710-1 UHF

Frequency Range	400 to 500 mc
Noise Figure	3.5 db to 5.5 db*
Gain & Bandwith	21 to 23 db—2 mc
Input & Output Impedance	50 ohms
Max. Input Level	100 mv
Panel Size & Wt.	3½ of 19-in. Rack Space—9¾ lb.
RF Connectors	Type 'N'
Power	115 vac, 50-60 cps, 15 watts
Tube Type	7077 Ceramic Triode
Circuit	Grounded-grid, 2 stages
Tuned Circuits	Three continuously tunable coaxial cavities of rigid brass tubing. Simple peaking adjustment only.

*Depending on tube selection

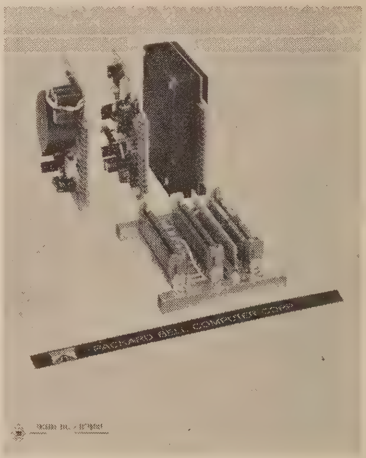
DC Amplifier

Packard Bell Computer Corp., a Division of Packard Bell Electronic Corp., 12333 West Olympic Blvd., Los Angeles 64, Calif., announces a completely solid-state DC amplifier, designated the DCA-1-B, which has the modularized plug-in feature illustrated in the photograph. This feature combined with the small size (4¾″ × 3½″ × 4¼″) permits greater design flexibility as it enables the design engineer to incorporate the amplifier in either a standard or nonstandard case.



The DCA-1-B is an operational, wide band, high accuracy amplifier with a solid-state chopper. Solid state design and the use of a non-mechanical chopper are said to make this a reliable instrument.

Specifications include: Frequency response exceeding −3 db at 200 kc; gain accuracy of ±0.03%; linearity and stability at ±0.02%; and drift of 500 µv referred to input.

Photoelectric Pulse Generator

A shaft-driven device that delivers electrical pulses at its output terminals is available from **W. & L. E. Gurley, Industrial**

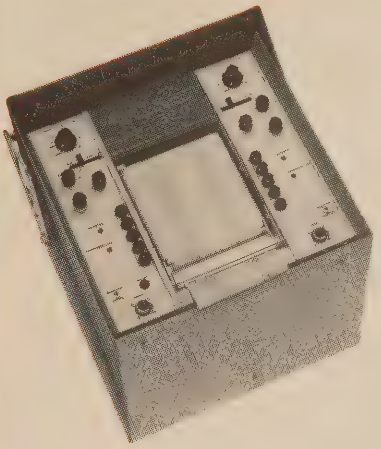
two channels



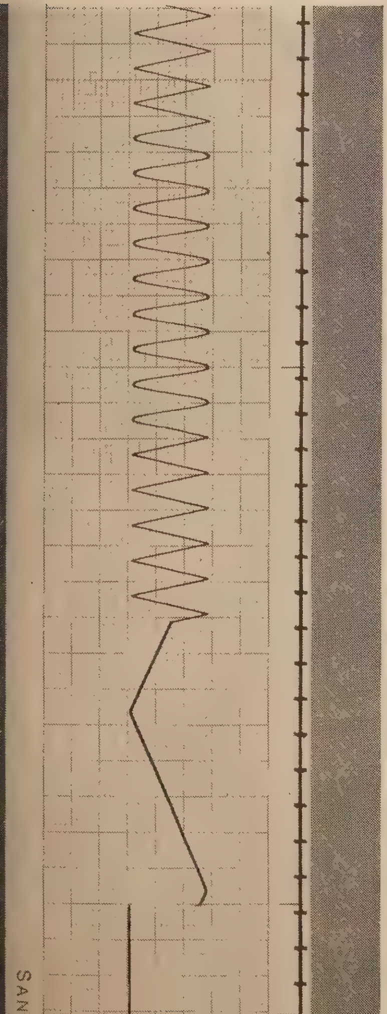
For General Purpose
DC Recording — Model 320

For recording *two variables* simultaneously, the Model 320 provides a versatile, transistorized amplifier for each input signal. The rugged 2-channel recorder assembly has heated stylus recording on two *50 mm wide* rectangular coordinate channels, 4 pushbutton chart speeds, and 6 inches of visible chart. The Recorder can be placed vertically, horizontally or at a 20° angle.

MODEL 320 SPECIFICATIONS

Sensitivity: 0.5, 1, 2, 5, 10, 20 mv/mm and v/cm
Frequency Response: 3 db down at 125 cps, 10 mm peak-to-peak
Common Mode Voltage: ±500 volts max.
Common Mode Rejection: 140 db min. DC
Calibration: 10 mv internal ±1%
Output Connectors for each channel accept external monitoring 'scope or meter

W SANBORN PORTABLE DIRECT WRITING RECORDERS FOR IN-PLANT, LABORATORY OR FIELD RECORDING



Two models of this 21 lb. brief case size recorder are available — Model 301 for AC strain gage recording, Model 299 for general purpose DC recording. Both provide immediately visible, inkless traces by heated stylus on 40 division rectangular coordinate charts . . . frequency response to 100 cps . . . 5 and 50 mm/sec chart speeds . . . approx. 4 inches of record visible in top panel window.

single channel

MODEL 301 SPECIFICATIONS

The amplifier section of the Model 301 is an all-transistorized carrier type with phase sensitive demodulator. The power supply and internal oscillator circuits are also transistorized.
Sensitivity: 10 uv rms/div (from transducer)
Attenuator Ratios: 2, 5, 10, 20, 50, 100, 200
Carrier Frequency: 2400 cps internal
Transducer Impedance: 100 ohms min.
Calibration: 40 uv/volt of excitation
Output Connector: for external monitoring 'scope or meter

MODEL 299 SPECIFICATIONS

Combines the dependability of transistors with the high input impedance of vacuum tubes for reliable broad-band DC recording.
Sensitivity: 10, 20, 50, 100, 200, 500 mv/div and 1, 2, 5 and 10 v/div
Input Resistance: 5 megohms balanced each side to ground
Common Mode Voltage: ±2.5 volts max. at 10 mv/div sensitivity increasing to ±500 volts max. at other sensitivities
Common Mode Rejection: 50:1 most sensitive range
Calibration: 0.2 volt internal ±1%
Output Connector: for external monitoring 'scope or meter

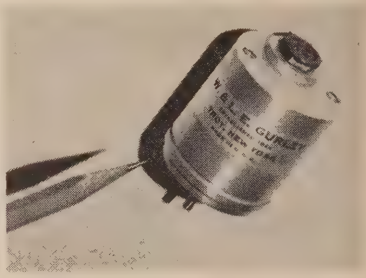
(Continued from page 178A)

Division, Troy, N. Y. The Model 8601 Photoelectric Pulse Generator may be used either as a rate generator or as an angle-measuring unit.



When used as a rate generator, the output frequency is read in terms of shaft speed. When used to measure angles, the total angle is determined by totalizing individual pulses. The pulses are generated by a light which passes to a photocell through rotating disc with alternating clear and opaque sectors. The number of pulses per revolution, therefore, is a function of the number of segments on the disc.

The Gurley Generator can be supplied

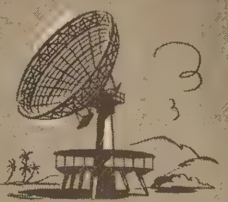
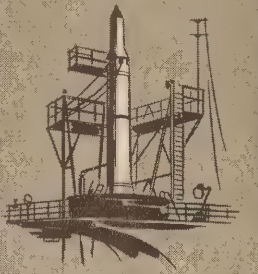
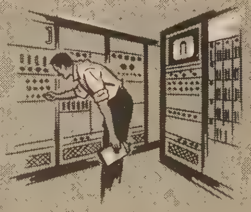
30 cps thru 70 mc frequencies available as tube type or transistorized oscillators.





BULOVA



NUMBER ONE SOURCE

in frequency control—components and systems

Today, an increasing number of electronic systems demand a degree of reliability heretofore unobtainable. That is why more and more manufacturers are specifying Bulova.

Bulova crystals, filters, ovens, packaged oscillators, and Bulova frequency control systems, custom-designed for either limited or mass production, meet and exceed military and industrial specifications.

Bulova's experience in mastering many of the most difficult problems involving component and system reliability has made it the *number one source* for frequency control devices. This experience can prove of immense value in your particular program. For more information write Dept. A-1183, today.

LING'S LIGHT-ARMATURE SHAKER LETS YOU TEST UNDER PRESSURE

Altitude, temperature, humidity! To help you conduct vibration tests under such extremes, Ling brings you the new liquid-cooled Shaker A246 of revolutionary design. In this 7500 force-pound shaker, Ling shaves the weight of the armature to a new low of only 68 pounds—the lightest armature by far for this force-rating. Structural resonance, first major, develops at 2570 cps, bare table. Shaker efficiency is at a new high; the A246 delivers full output at reduced amplifier power, cutting costs on associated electronics equipment. In a chamber, it functions at extremes well above ordinary shakers—from −100°F to +300°F, and up to 125,000 ft. Further, it simplifies chamber testing even more when used with the piggy-back chamber shown above. With Ling seals and baffles, the shaker body acts as one wall of the chamber, and only the table rides into the chamber. This is just one more advance from Ling research; for electronics that always help you out of prototype into production, *fast*—look to Ling. For details, write Dept. IRE-1, at either address below.

LING
ELECTRONICS

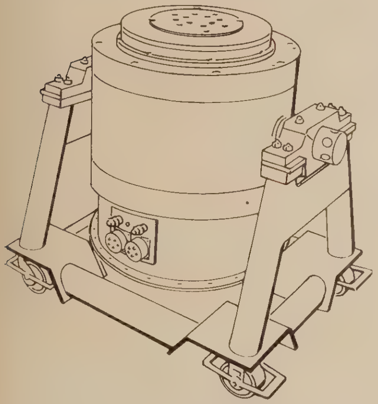
A DIVISION OF LING-ALTEC ELECTRONICS, INC. • 1515 SOUTH MANCHESTER, ANAHEIM, CALIFORNIA • 120 CROSS STREET, WINCHESTER, MASSACHUSETTS

LING ELECTRONICS

The new A246 shaker is but one of the advances growing out of Ling Electronics' continuing program of research and development. This program contributes to the many advantages enjoyed by the Ling customer—fast deliveries, sound engineering and design, ease of maintenance, and the compatibility of Ling environmental testing equipment with other systems.

The compatible design of the A246, for example, permits it to function as part of a test chamber—reducing the size of a chamber needed, and eliminating usual more costly installations. For this method, Ling also supplies a complete line of thermal barriers needed for piggy-back mounting, making combined-environment testing more practical.

Whatever your needs in high-power electronics—for vibration testing, acoustics or sonar—rely on Ling for truly practical design and advanced engineering.



Model A246 SHAKER, which is illustrated above, offers these other performance advantages: 7500 force pound rating, with high first resonance of 2750 cps. Engineered to operate continuously at maximum force on low input. Features simplified compensation over wide bandwidths, dual magnetic field structure for low stray field and improved force-current linearity.

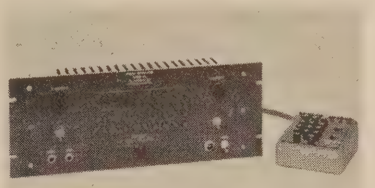
(Continued from page 180A)

with either photoresistive or photovoltaic cell. Output of the former cell consists of alternations between two levels of internal resistance; while output of the latter is a series of dc voltage pulses. Typically the output voltage is 0.1 to 0.25 v at 50K load impedance. Several standard disc patterns provide up to 500 pulses per revolution.

An illustrated bulletin is available.

Digital Translator

A new digital translator which accepts virtually any kind of digital data and provides an analog output plus control signals is now available from **F. L. Moseley Co.,** 409 N. Fair Oaks Ave., Pasadena, Calif.



The instrument, Model 42, permits automatic operation of Moseley Autograf or similar X-Y recorders. Accuracy of the digital-to-analog conversion is 0.1% and the accuracy of the recorders is maintained.

Model 42 is compatible with IBM summary punches and card readers including Models 514, 519, 523, 524, 526, etc. It may also be driven by mechanical punched tape readers such as Friden, Soroban solenoid and Teletype motorized readers, without modification to either the translator or driving equipment.

The new digital translator is supplied with a 10-key serial keyboard for manual input. The instrument accepts 4 digits and sine per axis and provides a front panel display of matrix contents.

Accessories available include a magnetic tape adapter, Flexowriter converter, remote decimal contents read-out panel and an optical magnetic tape converter.

Further information may be obtained from the firm.

Machine Tool Control Brochure Available

A new brochure describing numerical machine tool controls is now available from the **Industrial Systems Div., Hughes Aircraft Co.,** International Airport Station, Los Angeles 45, Calif.

The new control provides automatic positioning of a two-axis table from a preprogrammed punched one-inch tape. A third axis control can be added to the system.

The booklet gives a complete description of the unit, which can be applied to

IMPULSE

A DIGEST OF NEW DEVELOPMENTS IN ELECTRONICS AND AUTOMATION

PUBLISHED BY **ROME CABLE DIV. OF ALCOA**, ROME, N. Y.
PIONEERS IN INSTRUMENTATION CABLE ENGINEERING

STILL A MAN'S WORLD. More attention by designers of electronic equipment to the human factor is being called for by the people handling human engineering for the Air Force. Both operation and maintenance are involved. Typical deficiencies that may unnecessarily complicate maintenance, for example, are: insufficient or inadequate check points, extensive calibration requirements and the placing of high-failure-rate components in inaccessible spots. Ultimate goal is equipment designed so that required maintenance can be conveniently handled by those with a minimum of training in electronics.

UP TWENTY PER CENT. Though not completely clarified, the Defense Department's budget for 1961 in terms of military electronics looks like it will hit $5.5 billion. This is an increase of some 20 per cent over the 1960 figure.

SUN NEVER SETS. True to the traditions of the Empire yesteryear, the British will soon find another means of linking the members of the Commonwealth. This time it will be an undersea cable network that can carry slow-scan TV as well as telephony. The first link, between Britain and Canada, is scheduled for completion in 1961. By 1964 the second leg, tying Canada to Australia, will be ready. And so on.

TERA, GIGA, NANO AND PICO. These are the four prefixes that the National Bureau of Standards has picked following recommendation of the International Committee on Weights and Measures. These four join the already-in-use: mega, kilo, hecto, deka, deci, centi, milli and micro. Tera is 10^{12}; giga, 10^{9}; nano, 10^{-9}; and pico, 10^{-12}. Symbols for these new prefixes are, respectively, T, G, n and p. For example, 10^{-12} farad is a picofarad and is written in abbreviated form thusly: 1 pf.

JURY-SIZED SUB? The Navy is deep into a program (along with nine private firms and research groups) to put into the brine a fully automated sub that will need a crew of only 12. Automated and integrated will be the five fundamental control areas, or "loops": ship control, communications, engineering, weapons and environmental.

CABLEMAN'S CORNER. The old adage "Don't put the cart before the horse" was never so true as it is in these days of automation and instrumentation. With all the intricate pieces of equipment being designed these days, it is important that careful consideration be given to the wire and cable that may be employed in any system. Often forgotten is the unromantic aspect of the connecting links of the system. Cables are the arteries through which must flow the power and informational pulses necessary for reliable performance.

Don't take a chance on being able to obtain a cable that will fit into what is left. Many times, important characteristics such as conductor size, insulating walls, protective sheaths, flexibility and flex-life have to be sacrificed. Don't sacrifice reliability in your cables for an existing space or connector fittings.

For 100% reliability in multi-conductor cables, call on a cable specialist—and call on him as soon as possible. Phone Rome 3000, or write: Rome Cable Division of Alcoa, Dept. 1240, Rome, New York.

These news items represent a digest of information found in many of the publications and periodicals of the electronics industry or related industries. They appear in brief here for easy and concentrated reading. Further information on each can be found in the original source material. Sources will be forwarded on request. ⑰

KLYSTRONS AND MAGNETRONS

EMI

E.M.I. klystrons and magnetrons are available in a wide range of types and specifications to meet your particular and exacting requirements ■ Through the Hoffman Electron Tube Corp. — U.S. representative for E.M.I. — these tubes can be promptly delivered from inventory. Rugged, reliable E.M.I. klystrons and cavities range from 0.5 to 46.0 KMC . . . Magnetrons are available as packaged types for pulse operation; in "E", "Q", and "J" bands; forced-air cooled; indirectly heated cathodes; millimeter operation ■ E.M.I. Electronics Ltd. is one of the world's leading pioneers in the development of special and standard high-performance tubes for military and commercial use.

You can rely on E.M.I. for the highest standard of accuracy and reliability.

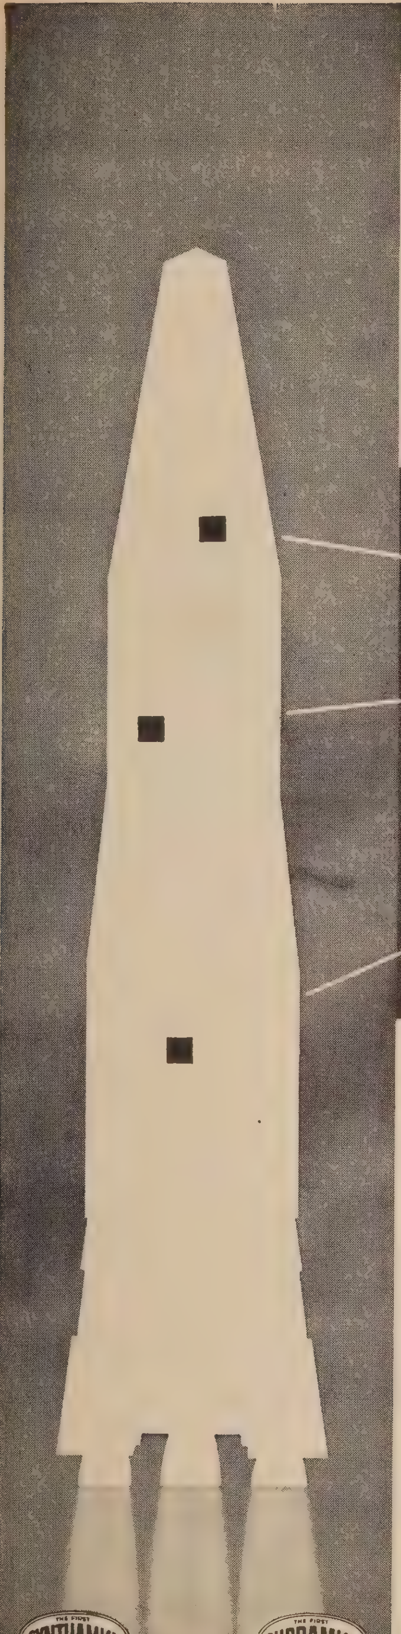
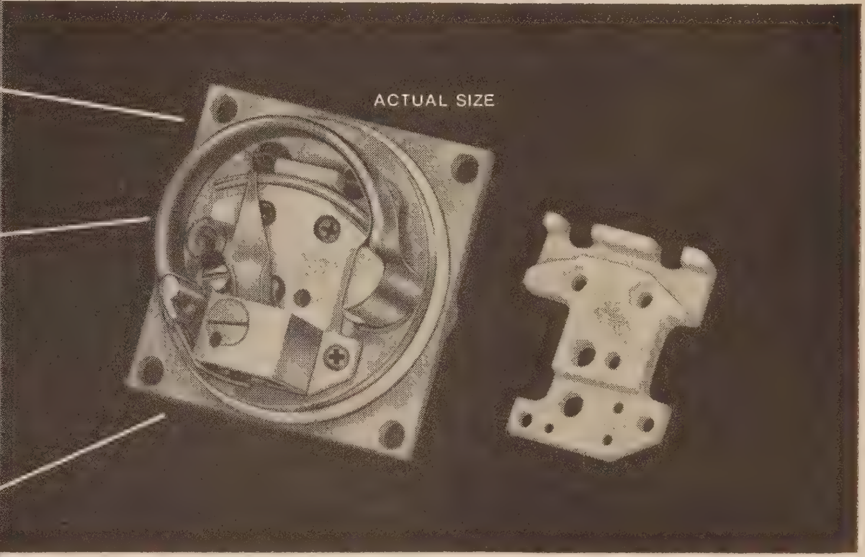
SUPRAMICA® 555 ceramoplastic

the world's most nearly perfect precision-moldable electronic insulation





for total reliability . . . at high temperatures . . . specified in BOURNS Inc. transducers

Why did Bourns, Inc. select SUPRAMICA 555 ceramoplastic as the insulating base for its ultra high-temperature differential pressure transducers?

Bourns' engineers cite three reasons . . . each a contribution to the total reliability of these airborne telemetering devices. "First is temperature. The sensitive element of the mechanism must withstand high operating temperatures. Next, SUPRAMICA 555 offers a combination of excellent insulating characteristics, which are essential to the highly accurate functioning of the potentiometer. In addition, this ceramoplastic material is readily moldable into complex shapes, such as that required for this intricate part."

For other applications SUPRAMICA 555 is used under operating conditions as high as +700°F. . . . SUPRAMICA 555 is one of the many ceramoplastic and glass-bonded mica insulation materials produced by Mycalex Corporation of America, in precision-molded and machinable formulations. Whatever your insulation need there is a Mycalex product to meet it—for example, SUPRAMICA 620 machinable ceramoplastic, which has a maximum operating temperature of +1550°F. Write today outlining your design problem for specific information.

VOICE *via* LIGHT BEAM

In Space . . . On Earth . . .

New power sources and electronic controls now permit transmission of voice communications between line-of-sight points using a narrow, high intensity beam of light . . .

FOR

- **Military applications requiring maximum security**
- **Civilian applications requiring privacy and where wires are not available**
- **Use in hazardous locations where radio waves could cause explosions or interference**

Electron Arc's power supplies are designed for use with high intensity light source lamps such as the Sylvania concentrated arc lamps. Complete units are available from 2 to 300 watts with varying light source diameters from 0.005 to 0.110 inch—with average brightness of 15,000 to 30,000 candles per square inch.

When used with the appropriate concentrated arc lamps, the system provides a ready and highly efficient source of *infrared* energy. Such units are finding extensive applications in communication and detection systems.

EA's line of power supplies and accessories for high intensity light sources are ideal for use in:

- **Laboratory instruments**
- **Photographic equipment**
- **Projection systems**
- **Photomicroscopy**
- **Collimating systems**
- **Medical and surgical equipment**

Other EA products include transformers and power equipment for special applications with a wide range of frequencies, and voltages to 100 kw and higher. DC power sources with controlled outputs and special voltages include rectifiers for higher voltages and currents than normally available.

New LAMBDA LA Series Condensed Data

DC OUTPUT:

(Regulated for line and load)

MODEL	VOLTAGE RANGE[1]	CURRENT RANGE[2]	PRICE
LA50-03	0-32 VDC	0- 5A	$395
LA50-03M	0-32 VDC	0- 5A	$425
LA100-03	0-32 VDC	0-10A	$510
LA100-03M	0-32 VDC	0-10A	$540

[1] The output voltage for each model is completely covered in four steps by selector switches plus vernier control and is obtained by summation of voltage steps and continuously variable DC vernier as follows:

MODEL	VOLTAGE STEPS
LA 50-03, LA 50-03M	2, 4, 8, 16 and ±2 volt vernier
LA100-03, LA100-03M	2, 4, 8, 16 and ±2 volt vernier

[2] Current rating applies over entire output voltage range

Regulation: Line: Better than 0.15 per cent or 20 millivolts (whichever is greater). For input variations from 100-130 VAC. Load: Better than 0.15 per cent or 20 millivolts (whichever is greater).

Transient Response: Line or Load: Output voltage is constant within regulation specifications for step function line voltage change from 100-130 VAC or 130-100 VAC or for step-function load change from 0 to full load or full load to 0 within 100 microseconds after application.

Ripple and Noise: Less than 1 millivolt rms with either terminal grounded.

AC INPUT:

100-130 VAC, 60 ± 0.3 cycles[3]

[3] Well within standard commercial power line frequency tolerances in the United States and Canada.

OVERLOAD PROTECTION:

Electrical: Magnetic circuit breaker front panel mounted. Special transistor circuitry provides independent protection against transistor complement overload. Fuses provide internal failure protection. Unit cannot be injured by short circuit or overload.

REMOTE SENSING:

Provision is made for remote sensing to minimize effect of power output leads on DC regulation, output impedance and transient response.

PHYSICAL DATA:

Size:
LA 50-03 . . . . 5¼″ H x 19″ W x 14⅜″ D
LA100-03 . . . . 7″ H x 19″ W x 14⅜″ D

Panel Finish: Black ripple enamel (standard). Special finishes available to customers specifications at moderate surcharge. Quotation upon request.

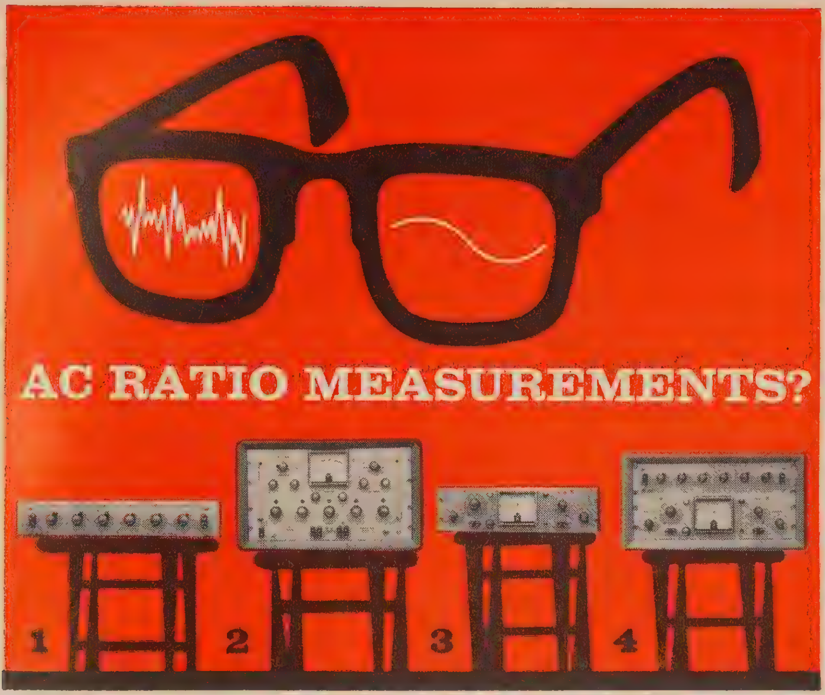
λ LAMBDA ELECTRONICS CORP.



THERE'S A NORTH ATLANTIC INSTRUMENT TO MEET YOUR REQUIREMENTS, TOO...

Now—from North Atlantic—you get the complete answer to AC ratio instrumentation problems—in the laboratory, on the production line, in the field.

Specialists in ratiometry, North Atlantic offers the only complete line of precision instruments to handle any ratio measurement task. All are designed to meet the most demanding requirements of missile age electronics—provide high accuracy, flexibility, component compatability and service-proven perforformance. Some are shown above.

If your project demands total solution to ratio measurement problems, write for Date File No. 10M It provides complete specifications and application data and shows how North Atlantic's unparalleled experience in ratiometry can help you.

1. RATIO BOXES:	2. COMPLEX VOLTAGE RATIOMETERS	3. PHASE ANGLE VOLTMETERS	4. RATIO TEST SETS
Both laboratory standards and general duty models. Ratio accuracies to 0.0001%. Operation from 25 cps to 10 kc.	Integrated, single-unit system for applications where phase relations are critical. Accuracy to 0.0001%, unaffected by quadrature. Three frequency operation. Direct reading of phase shift in milliradians or degrees.	Versatile readout system for all ratiometry applications, providing direct reading of phase, null, quadrature, in-phase and total voltage. Broadband, single-, or multiple-frequency operation.	Ratio reference and readout in one convenient package for production line and similar applications. Can be supplied with any desired combination of ratio box and phase angle voltmeter.

TUBE PROBLEM:

The Armed Forces needed a new version of the 6J4 reliable tube type which would provide a tube life of almost 1000 hours. Existing tubes of this type had an average life of only 250 hours. In addition, this new tube had to be produced under ultra-high quality control standards.

SONOTONE SOLVES IT:

By making improvements in the cathode alloy and setting up extremely tight controls in precision, manufacture and checking, Sonotone engineers produced a 6J4WA with a *minimum* life of 1000 hours... most running *much longer.*

RESULTS:

The Sonotone 6J4WA is one of three reliable tubes now being manufactured under U.S. Army Signal Corps RIQAP (Reduced Inspection Quality Assurance Program), monitored by the U.S. Army Signal Supply Agency. And the same rigid quality standards apply to Sonotone's entertainment type tubes as well.

Let Sonotone help solve *your* tube problems, too.

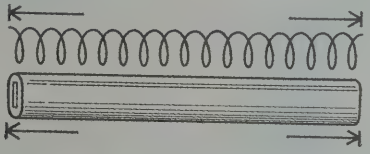
BOURNS TRIMPOT® WITH BUILT-IN TEMPERATURE STABILITY

Stable settings under extreme temperature conditions is an outstanding feature of the Trimpot® potentiometer. This thermal stability is built-in through all phases of design and production—

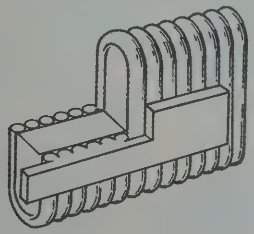
MATCHED COEFFICIENTS OF THERMAL EXPANSION

Resistance wire and mandrels have matched coefficients of thermal expansion to reduce the "strain gage effect." Linear expansion rates for the mandrel and wire match so closely that the temperature coefficient value for the entire wirewound element approximates that of the wire itself.



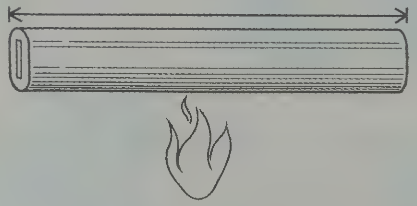
EXCLUSIVE SILVERWELD® TERMINATION

Silverweld is an actual metal-to-metal fusion of element wire and external terminal. In doing away with mechanical or soft-solder joints, Bourns eliminates potential hot spots thus extending the potentiometer's temperature range. The fusion of the Silverweld terminal to many turns of wire on the resistance element avoids the problem of single wire termination. Silverweld is virtually indestructible under thermal stresses.



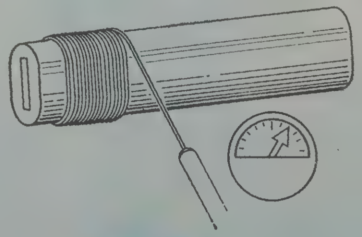
THERMALLY STABLE CERAMIC MANDRELS

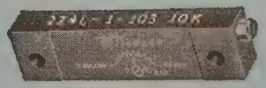
Bourns takes advantage of high thermal stability of ceramic materials for element mandrels. Today, all Bourns Trimpot potentiometers provide the improved performance and reliability afforded by ceramic materials.



EXCLUSIVE TENSION CONTROL EQUIPMENT

Bourns has developed specialized winding equipment that provides constant and precise control of wire tension during winding operations. "Necking" of the wire or resistance-altering stresses never occur. Instead the wire remains uniform—well able to withstand temperature variations with no appreciable change in resistance.





Specify Trimpot—the original leadscrew-actuated potentiometer with reliability on which you can depend. 20 basic models—4 terminal types—3 mounting styles.

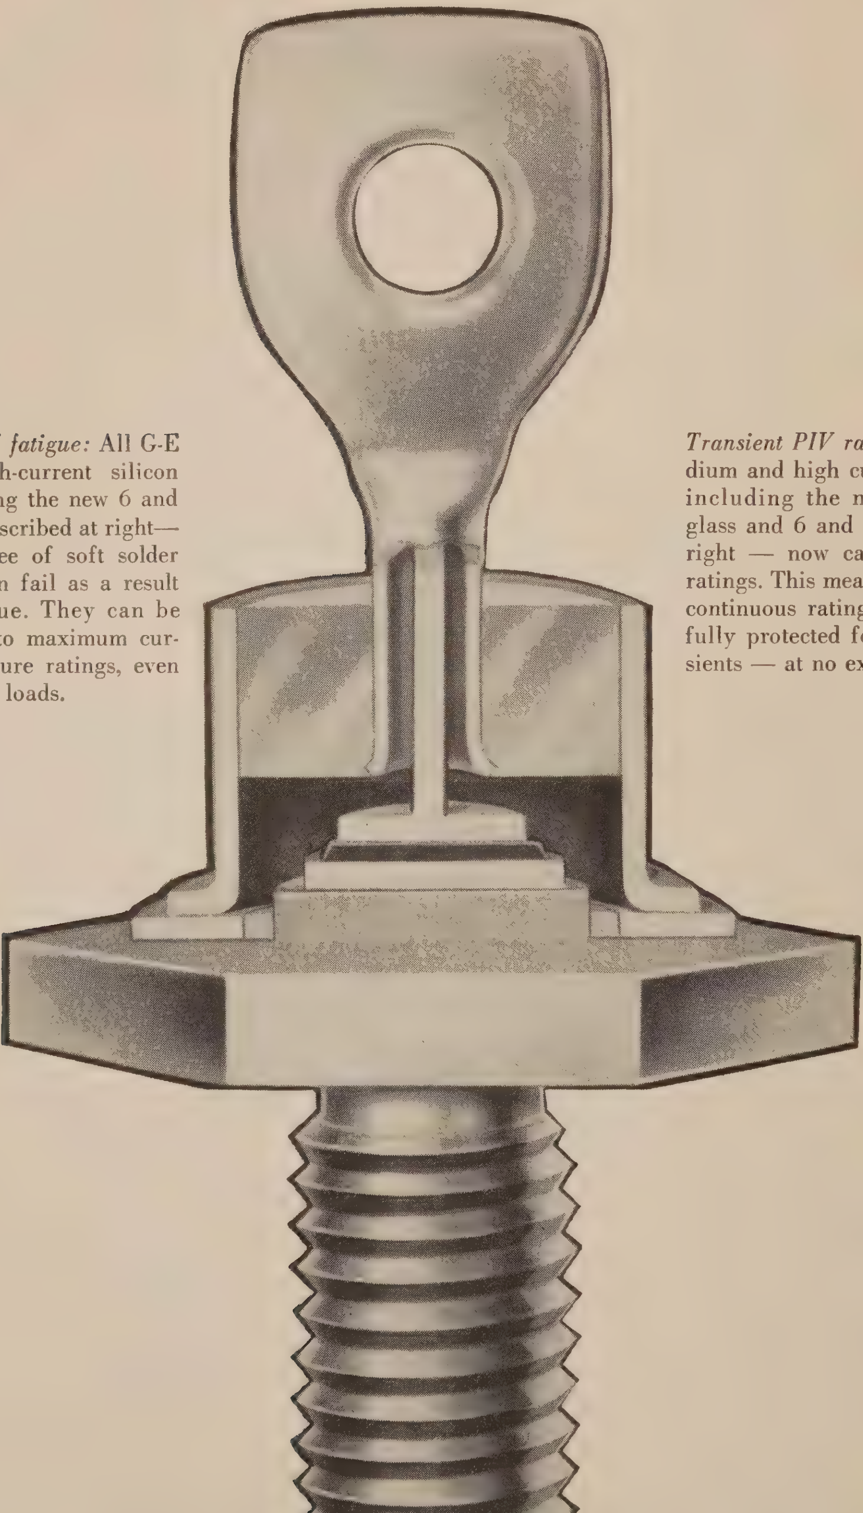
NEW RECTIFIERS FROM

Free from thermal fatigue: All G-E medium and high-current silicon rectifiers—including the new 6 and 12-amp. devices described at right—are completely free of soft solder joints, which often fail as a result of thermal fatigue. They can be worked right up to maximum current and temperature ratings, even on highly cyclical loads.



Transient PIV ratings. All G-E medium and high current rectifiers — including the new subminiature glass and 6 and 12-amp. devices at right — now carry *transient* PIV ratings. This means you can buy the continuous rating you need and be fully protected for occasional transients — at no extra cost!

GENERAL ELECTRIC

New Silicon Subminiature Glass Rectifier

Designed for maximum thermal conductance over a wide temperature range. Suitable for MIL-E-1/1143. Extremely low leakage currents. Ideal for magnetic amplifier, blocking and other low-leakage applications.

JEDEC or GE Type Number	Repetitive PIV	Transient PIV	Max. I_{DC} at T°C	Max. Lkge Cur. (Full cycle Av.)	Max. Full Load Voltage Drop (Full cycle Av.)	Max. Oper. Temp.

1N676-1N679, 1N681-1N687 and 1N689 also available in this package.

New Silicon Insulated Stud Mounted Junction Rectifier

Designed for applications requiring fins or direct chassis mounting. Stud electrically insulated from rectifying junction. High forward currents permitted at case temperatures up to 150°C (up to 165°C with derating). Reverse current at maximum junction temperature extremely low, making these devices ideal for low-leakage applications.

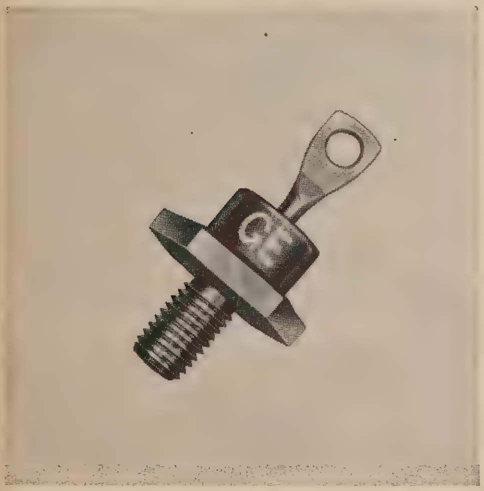
New Silicon Medium Current 6 and 12-amp. Junction Rectifiers



With these new devices, General Electric now offers the widest selection of rectifiers in the medium current range. Designed for all rectifier applications from 2 to 15 amperes. Extremely low forward voltage drop and thermal impedance combined with high junction temperature rating permit high current operation with minimum space requirements. May be mounted directly to chassis or fin or electrically insulated from heat sink by using mica washer kit provided with each unit.

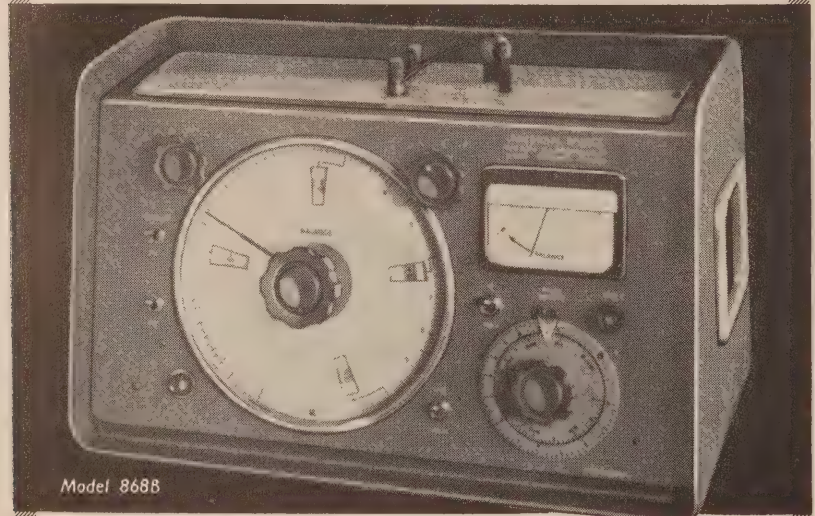
GENERAL ELECTRIC

THE NEW MARCONI UNIVERSAL BRIDGE

Gives NEW Simplicity in LCR Measurements



L — 1 μH to 100 henrys
C — 1 μμF to 100 μF
R — 0·1 ohm to 100 MΩ

•Direct read-out with no multiplying factors, eliminates operator errors. •Model 868 B also has precision Q and tan δ (D) dials. Inductance and capacitance are measured at 1 or 10 kc/s in an R-C ratio-arm bridge; resistance at d.c. in a Wheatstone bridge. The bridge detector gives positive indication of the direction of balance point even when far off-balance; as a result, components whose values are completely unknown can be evaluated in a few seconds with the minimum of searching. Detector a.g.c. eliminates the need for sensitivity controls.
Also available—**Low Capacitance Bridge Model 1342:** 0·002μμ F to 1,111μμ F; 3-terminal transformer ratio-arm bridge designed for precision measurement of extremely low capacitance.
For full details, write for leaflet D171.

Horizons Unlimited

Development of a high-performance inertial guidance system of unprecedented performance for long-range guided missiles, satellites and space vehicles has been announced by Bell Aircraft Corporation's Avionics Division.

Bell Avionic's engineers describe the highly-classified system as "the most successful and reliable of any new inertial instrumentation concepts so far tested."

The system was developed under the direction of Dr. Helmut W. Schlitt, recognized within the industry as an outstanding authority in the field of inertial guidance.

The new system has undergone extensive flight tests at the Niagara Falls, N.Y., Municipal Airport. Some of its components already are being used in guided missiles.

Bell Aircraft's Avionics Division also is engaged in many other important programs, including Battlefield Monitoring Systems, All-Weather Automatic Aircraft Landing Systems and Secure Data Link Systems.

The Avionics Division recently has joined with Pan-American World Airways, Inc. to find a solution to the serious problem of radio interference with the operation of Army combat electronic equipment.

Bell and Pan-Am's Guided Missiles Range Division will set up an electronic environmental test facility and drone test range near Fort Huachuca, Ariz., to track down the source of the interference, submit recommendations for corrective action and initiate procedures to eliminate these conditions.

Experienced engineers and scientists are needed for all of these programs. For information, write George Klock, director of engineering employment, today.

F-28/APN-19 FILTER CAVITY
Jan. spec: Tuneable 2700-2900mc, 1.5db max. loss at ctr freq over band. Details: Insertion loss variable. Single tuned filter for freq channelling in radar beacon. Invar center tuning conductor ¾ wavelength. New $37.50 each.

2C40 LIGHTHOUSE CAVITY
AN/APW-11A transmitter cavity for 2C40. Complete S band coverage at max. power. Temperature compensated. New $77.50 ea.

AN/APS-10 3CM. X BAND RADAR
Complete RF head including transmitter, receiver, modulator. Uses 2J42 magnetron. Fully described in MIT Rad. Lab. Series Vol. I, pps. 616-625 and Vol. II, pps. 171-185. $375.00. Complete X band radar system also avail. incl. 360 deg. antenna, PPI, sync, pwr supply. Similar to $17,000 weather radar now in use by airlines $750 complete.

10 CM. WEATHER RADAR SYSTEM
US Navy Raytheon 275 KW peak output S band. Rotating yoke Plan position Indicator. Magnetron supplied for any S band frequency specified, incl. Weather Band. 4, 20 and 80 mile range. 360 degree azimuth scan. Sensitive rcvr using 2K28/707B and 1N21B. Supplied brand new complete with instruction books and installation drawings. Can be supplied to operate from 32VDC or 115 volts. Price $975. Ideal for weather work. Has picked up clouds at 50 miles. Weight 488 lbs.

SUMMATION BRIDGE
TS 731/URM. Portable, general purpose, field type, ruggedized wattmeter used to measure R.F. power output of radio, radar & navigation equips. A direct reading summation type circuit in which a bolometer acts as one arm of a D.C. Weatstone bridge, at the same time providing correct resistivity termination for R.F. entering the wattmeter. Power supply: 115-VAC, 1 ph.50-1600 cy. Freq. range: 1000 to 4000 mcs with plumbing supplied. VSWR less than 1.3 Gov't cost well over $1000 in large quantity. Your cost—$395 ea. Factory new.

AN/APN-60
10 CM. RADAR BEACON FOR GUIDED MISSILES. 14″ pressurized housing. 2C40 lighthouse OSC. Trans-revr. unit $275.00.

⅞″ RIGID COAX. RG44/U 50 ohm, standard fittings. 10cm stub supported. 12 ft. lengths. Silver plated. New $34.50 each. 12 ft. length. Right angle bends $6 ea.

X BAND HORN. Waveguide feed pressurized window. 180 Deg. feed back. New $22.50.

TOPWALL HYBRID JUNCTION. 8500-9600mc 1x.5 wg size. Broad banded better than 16%. Aluminum casting. $15.00 new. Crossover output. 1x.5 wg size. $5.00 new.
BROAD BAND BAL MIXER using short slot-hybrid. Pound type broad band dual balanced crystal holder. 1x.5 wg size. $25.00 new.

FLEXIBLE WAVEGUIDE. 1x.5 X band 4″, new $5.00. 1x.5 X band 9″ Technicraft. New $10.00. 1.5 X band 24″ Airtron. New $21.50. 1¼″ x ⅝″ X band 12″ Western Elec. New $19.50.
RG48 TO ⅞ COAX. ADAPTER S Band 1½ x 3″ W.G. to RG 44/U coax. New. $26.50.
COAX MIXER ASSEMBLY S BAND IN21 type crystal detector RF to IF, 'N' fittings, matching Slug, duplex couplings, mf. G.E. New, $18.50.

3 & 10 CM COMPLETE SCR 584 RADARS

AUTOMATIC TRACKING RADAR
Our 584s in like new condition, ready to go, and in stock for immediate delivery. Ideal for research and development, airway control, GCA, missile tracking, balloon tracking, weather forecasting, antiaircraft defense, tactical air support. Write us. Fully Desc. MIT Rad. Lab. Series, Vol. I, pps. 207-210, 228, 284 286.

AN/MPN-1B GCA SET
Ground control approach equipped trailer with 3 cm precision and 10 cm search radars plus full complement precision and search indicators. All in original trailer. Call—write for info. and price. Fully Desc. MIT Rad. Lab. Series, Vol. II, pps. 237-251.

AN/FPN-32 GCA RADAR
Lab. for Electronics "Quad" type portable ground control approach radar system. 3cm. search and precision approach. Complete systems in used, good condition. A very late type system—in stock $5500 ea.

MIT Model 9 PULSER
1 MEGAWATT-HARD TUBE
Output pulse power 25KV at 40 amp. Max duty ratio: .002. Uses 6C21 pulse tube. Pulse duration .25 to 2 microsec. Input 115 volts 60 cycle AC. Includes power supply in separate cabinet and driver. Fully guaranteed as new condition. Full Desc. MIT. Rad. Lab. series "Pulse Generators."

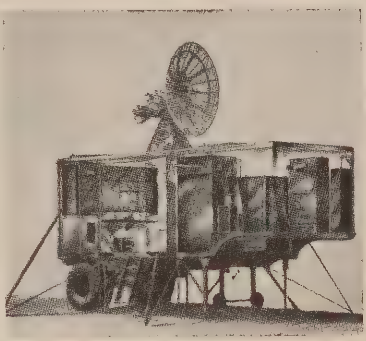
24KMC. PKG. MAGNETRON
3J21 Magnetron. 60kw output at 1.25cm, K band. 15kv 15 amp. input. Axial cathode mount. Waveguide output. Packaged with magnet. New $87.50 ea. gtd.

SPERRY KLYSTRONS
SMX-32 Amplifier-Multiplier 9.0-10.5-KMC. Amp. freq. multiplier; output power 1.5 to 2 watts at 9000 to 10,500 mc; drive freq. 4500 to 5250 mc. New in original sealed cartons. Guaranteed 90 days. Regular price $925 ea. Our price $425 ea.
SMC-11A Frequency multiplier. Output range 4640-4670 mc. ½ to 1 watt on 6th harmonic. Input range 773-778 mc. For direct control of microwave frequencies. New in original sealed cartons. Guaranteed 90 days. Regular price $1500 ea. Our price $495 ea.

2 MEGAWATT PULSER
Includes Rectifier xfmr 5800/7000V, 2.2/2.55-KVA; Resonant charging choke 150 cy. 30H 12 Amp. Ins. 17KV; Capacitor network 17E2-2-300-25P2T; Capacitor .04Mfd. 17KVDC; Transformer 4400V to 22,000V; Fil. Xfmr. & Filter choke 5.1V 18Amp, 6 H .21Amp. DC; 4C35 pulser, 3B24W (6 each), WL1B41 gap tube. Price new type MD-53/APS20C $1125.00

AN/SPT-6A TRANSMITTER
350 to 1400mc countermeasures jammer. 115V 60 cy AC input. New and complete operating unit. $750.00

FM 3CM. SIGNAL GENERATOR
TS-263/TPS-10 X band FM signal generator. Tunes 9KMC band. With calib. atten. Regulated pwr supply. New $325.00
TAPER. RG51 to RG52 (1¼ x ⅝″ to 1 x ½″) Smooth Electroform. Standard Flankes. New $16.50.



SCR 584 ANTENNA SYSTEM

Full azimuth and elevation sweeps. 360 degrees in azimuth. 210 degrees in elevation. Accurate to 1 mil. over system. Complete for full tracking response. Includes pedestal drives, selsyns, po-Excellent used condition. This is the first time tentiometers, drive motors, control amplidynes. Excellent used condition. This is the first time these pedestals have been available for purchase. Limited quantity in stock for immediate shipment. Ideal for antenna pattern ranges, radar systems, radio astronomy, any project requiring accurate response in elevation and azimuth. Compl. operations console all housed in trailer.
Complete description in McGraw-Hill Radiation Laboratory Series, Volume I, page 284 and page 209, and Volume 26, page 233.

RT39/APG-5 & 15 10CM RADAR. Complete S band RF package. Lighthouse 2C40 xmtr. 2C43 rcvr, TR. 829B pulser, miniature 6AK5 IF strip. Press. 12″ dia., 24″ lg. New with tubes $275. Ref: MIT Rad. Lab. Series Vol. I, pg. 207.

74 to 320 MC BUTTERFLY TUNER
Rotates thru 360 deg. either hand or motor driveable. New, $22.50 ea.

VG-12″ PROJECTION PPI RRTR $395.00.
CPS-1, PPI 12″. NEW, $275.00.

TS-743/U SIGNAL GENERATOR
15,250 to 16,250mcs, calibrated attenuator, 115VAC regulated power supply. Mfg. Polarad. Exc. condition $1250. each.

KLYSTRON MOUNTS
3CM. Precision Tube Mount. Waveline model 688. X band shielded klystron mount PRD signal generator type. Complete with variable glass vane attenuator. Brand new. $205. list. Price $45.00.
S. band. Type N output. Tunable over entire band. For Shepard type tube i.e. 726 w/socket & tube clamp. Mfg. GE. New, $15.00.
K band. 2K50 output cplg. w/90 deg. H bend. New. $19.50.

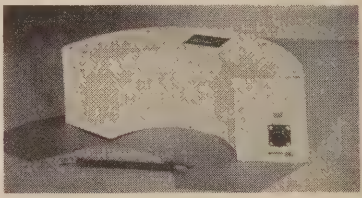
"Shaped" Battery With Dual Voltage

A special, "shaped" electric APU power source containing two separate battery sections developed by **Cook Co.,** a subsidiary of **Telecomputing Corp.,** 3850 Olive St., Denver 7, Colorado, provides dual output for missile and spacecraft power requirements. The two battery sections in the Model P68A provide two different voltage levels.



One section provides a current of 8 amperes at 28 volts. Maximum current is 25 amperes, with a discharge time of 40 minutes at 8 amperes. Capacity is 5.5 ampere-hours.

The second section supplies 6.3-volt power at 3 amperes. Discharge time is 40 minutes. Maximum current is 25 amperes. Capacity is 5.5 ampere-hours.

Both sections are activated automatically. The activating mechanism is an electrolyte tank and piston arrangement, operated by a solid propellant gas generator. Activation time is 1 second. The signal required is 2 amperes at 28 volts.

The cells are specially designed for automatic activation and have foil anodes enclosed in sealed separators. This technique eliminates the problems of anode gassing and internal shorts. The entire unit is hermetically sealed to prevent leakage or contamination. The battery weighs 13 pounds.

The Model P68A will withstand shock to 50 g, acceleration to 20 g and vibration to 10 g, along all three major axes. Temperature range is from 50°F to 150°F, with special models providing ranges of −65°F to +165°F. Thermostatically controlled heaters are available.

Case material is steel. Mounting configuration is supplied to customer specifications. Standard or special connectors and terminals may be specified.

A fail-safe detection circuit may be provided for protection against premature activation. A double estimated activation ignition circuit overcomes shorts or open circuit failures. The estimated shelf life is 5 years.

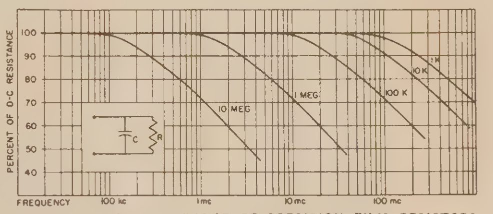
‡ Other resistance values and tolerances available on special order

For a more detailed discussion of this subject, contact your nearest TI sales office for a copy of "High-Frequency Characteristics of Precision Film Resistors."

In high frequency applications, precision film resistors are superior to composition or wirewound resistors; skin effect of the thin film is negligible.

OHMIC VALUE vs FREQUENCY

Precision film resistors of a given physical size have the same distributed capacitances regardless of their ohmic value. As the frequency increases, the shunting effect of the distributed capacitance causes the effective parallel resistance to decrease. The reactance of the stray capacitance becomes a relatively good shunt when it approximates the ohmic value of the resistor. The smaller the ohmic value of a precision film resistor (for a given physical size), the higher its usable frequency range.



HIGH FREQUENCY RESISTANCE OF PRECISION FILM RESISTORS

INDUCTANCE CONSIDERATIONS

The inductance caused by helixing the higher value resistors is negligible throughout the "useful" range of frequencies at which the resistance is greater than 60% of its d-c value.

When resistors under 500 ohms are measured using high frequency meters, the reactive component of the equivalent parallel circuit appears inductive because of lead and binding post inductance. However, the resistor itself is capacitive.

TI TYPE	SIZE (WATT RATING)				
	⅛	¼	½	1	2
MIL-LINE (CD)	0.2	0.1	0.25	0.5	0.6
MOLDED (CDM)	0.3	0.25	0.45	0.7	0.7
HERMETICALLY SEALED (CDH)	0.3	0.25	0.45	0.75	0.8

CAPACITANCE IN μμf OF TI PRECISION FILM RESISTORS

CAPACITANCE CONSIDERATIONS

The average measured capacitance of Texas Instruments Precision Film Resistors is determined primarily by the end cap-to-cap capacitance which is proportional to the dielectric constant of the core and encapsulating material.

MOUNTING

Precision film resistors of 200 ohms or less perform satisfactorily at 5000 mc and higher if placed in a well-designed coaxial mount. A coaxial mount constructed from a standard UG-18B/U Type N plug can be used effectively. In conventional terminals, correct mounting of the body of the resistor off the circuit chassis and the use of short leads will minimize the stray capacitance and lead inductance.

Correction Notice

Delay Lines

By using a new principle in delay network design, a new series of delay lines with ratio of rise time to total delay less than 0.02 has been achieved by **Ad-Yu Electronics Lab., Inc.**, 249–259 Terhune Ave., Passaic, N. J. Besides the feature of producing very fast rise time, the attenuation can be minimized to be less than 0.02 db per 1/10-microsecond delay. Two or more units of Type 10T series can be connected in tandem for longer delay whenever their impedances are identical. In this case, the time delay will be equal to the sum of the delay of each unit and the rise time will be approximately equal to the square root of the sum of the squares of the rise time of each unit.

The features of this delay line series can be summarized as follows: (1) The ratio of rise time total delay can be made less than 0.02. (2) The distortion is generally less than 2%. (3) The attenuation can be made less than 0.2 db per microsecond delay. (4) Physical size can be made less than 2 cubic inches per microsecond delay. (5) The temperature coefficient is less than 50 parts per million per degree Centigrade. (6) All types of this series can also be made to meet existent MIL specifications. The characteristic impedance ranges from 50 ohms to 1000 ohms. The time delay per 10 sections ranges from 0.25 microsecond to 5 microseconds. The accuracy of delay is less than ±1.5%.

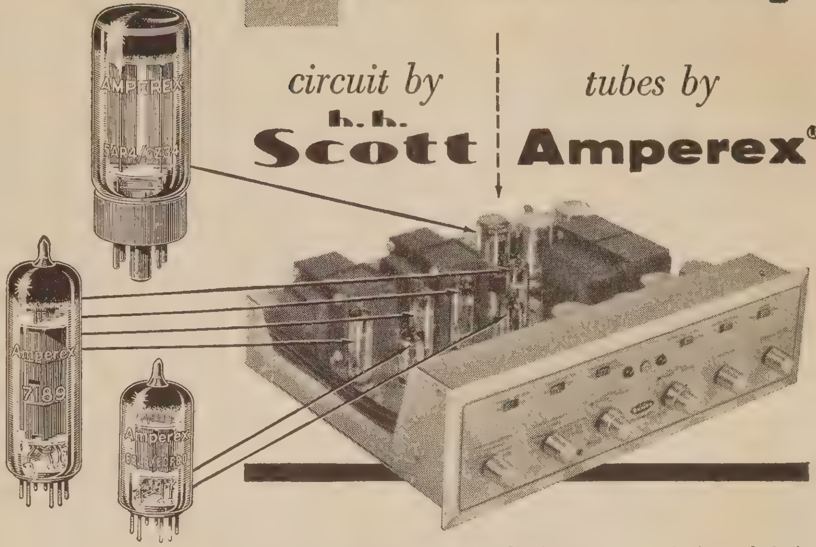
2 for the money

circuit by
h. h. Scott

tubes by
Amperex®



H. H. Scott engineers, preliminary to the design of their *Model 299 (40 Watt) Complete Stereo Amplifier,* canvassed the industry for tube types offering something truly exceptional in the way of reliability, low distortion, low noise, low hum and absence of microphonics.

As has frequently been their experience, the people at Scott found these qualities best exemplified by Amperex tubes. Thus, the tube complement of the Scott Model 299 includes four Amperex 7189's, one Amperex 5AR4/GZ34, and two Amperex 6BL8/ECF80's.

These and many other Amperex 'preferred' tube types have proven their reliability and unique design advantages in the world's finest audio components.

Applications engineering assistance and detailed data are always available to equipment manufacturers. Write: Amperex Electronic Corp., Special Purpose Tube Division, 230 Duffy Ave., Hicksville, Long Island, New York.

6BM8/ECL82: Triode-pentode, 8 w., push-pull

VOLTAGE AMPLIFIERS
6267/EF86: Pentode for pre-amps
12AT7/ECC81: } Twin triodes, low hum, noise and microphonics
12AU7/ECC82:
12AX7/ECC83:
6BL8/ECF80: High gain, triode-pentode, low hum, noise and microphonics

RF AMPLIFIERS
6ES8: Frame grid twin triode
6ER5: Frame grid shielded triode
6EH7/EF183: Frame grid pentode for IF, remote cut-off
6EJ7/EF184: Frame grid pentode for IF, sharp cut-off
6AQ8/ECC85: Dual triode for FM tuners
6DC8/EBF89: Duo-diode pentode

RECTIFIERS
6V4/EZ80: Indirectly heated, 90 mA
6CA4/EZ81: Indirectly heated, 150 mA
5AR4/GZ34: Indirectly heated, 250 mA

INDICATORS
6FG6/EM84: Bar pattern
IM3/DM70: Subminiature "exclamation" pattern

SEMICONDUCTORS
2N1517: RF transistor, 70 mc
2N1516: RF transistor, 70 mc
2N1515: RF transistor, 70 mc
IN542: Matched pair discriminator diodes
IN87A: AM detector diode, subminiature

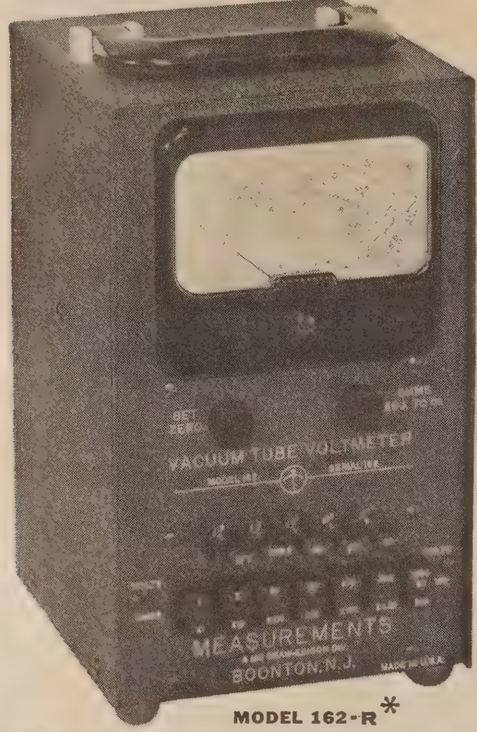
MEASUREMENTS' NEW

VACUUM TUBE VOLTMETER



MODEL 162-R*

Provides RANDOM ACCESS to all functions and ranges through the use of push-button switches.

- For voltage and current measurements in laboratories, service shops and on production lines.
- For accurate rf and ac voltage measurements from 0.1 to 300 volts on electronic equipment from the low audio range through the VHF range.
- For dc voltage measurements from 0.01 to 1000 volts without disturbing circuit performance.
- For direct current measurements as low as 0.001 microampere.

*Ohms range 0.2 ohms to 500 megohms in 7 decades with 10; 100; 1,000; 10,000; 100,000 ohms, 1 megohm and 10 megohms mid-scale rating.

Price: $210.00 F.O.B. Boonton

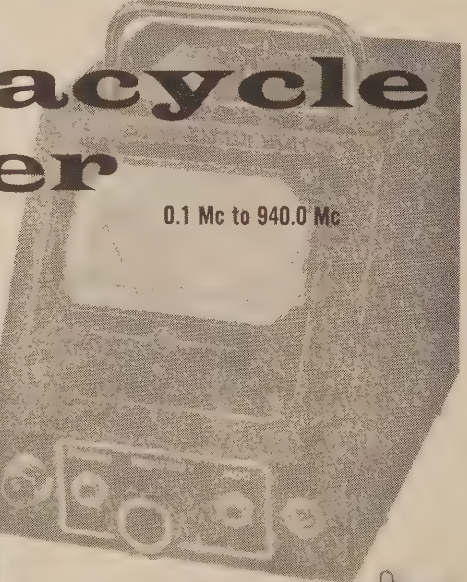
Megacycle Meter



0.1 Mc to 940.0 Mc

Determines resonant frequency of tuned circuits, antennas, transmission lines, by-pass condensers, chokes, etc. Measures inductance and capacitance. Also used as a signal generator, wave meter, frequency meter, and in many other applications.

This compact, lightweight grid-dip meter is available in the frequency ranges indicated.

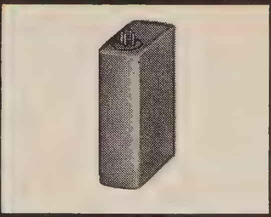
DAR ANTENNA:

For Your Special Applications

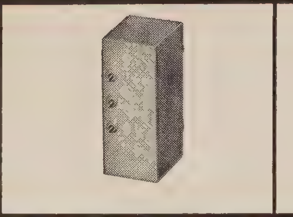
The bulk of UTC production is on special units designed to specific customers' needs. Illustrated below are some typical units and some unusual units as manufactured for special applications. We would be pleased to advise and quote to your special requirements.

FILTERS

All types for frequencies from .1 cycle to 400 MC.

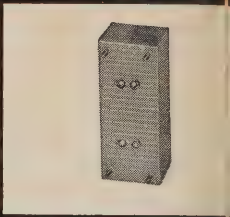


400 ∼ telemetering, 3 db at ± 7.5%, 40 db at 230 and 700 ∼, ⅝ x 1¼ x 2″



15 ∼ BP filter, 20 db at 30 ∼, 45 db at 100 ∼, phase angle at CF less than 3° from —40 to + 100° C.

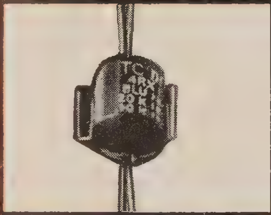
LP filter within 1 db to 49 KC, stable to .1 db from 0 to 85° C., 45 db at 55 KC.



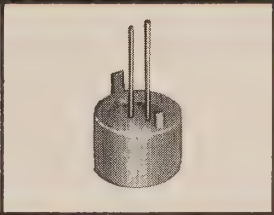
LP filter less than .1 db to 2.5 KC, 50 db beyond KC.

HIGH Q COILS

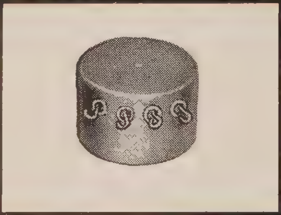
Toroid, laminated, and cup structures from .1 cycle to 400 MC.



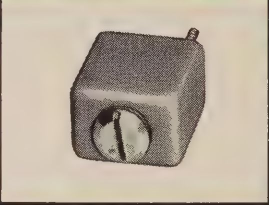
Tuned DO-T servo amplifier transformer, 400 ∼ .5% distortion.



Toroid for printed circuit, Q of 90 at 15 KC.



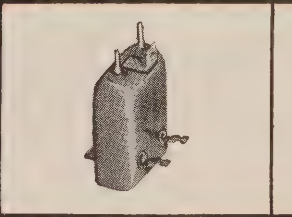
Dual toroid, Q of 75 at 10 KC, and Q of 120 at 5 KC.



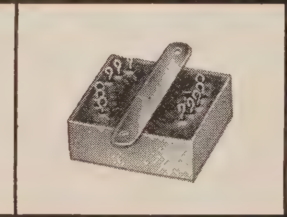
HVC tapped variable inductor for 3 KC oscillator.

SPECIALTIES

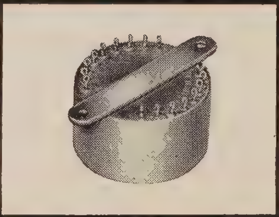
Saturable reactors, reference transformers, magnetic amplifiers, combined units.



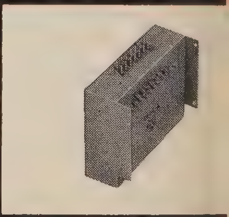
RF saturable inductor for sweep from 17 MC to 21 MC.



Voltage reference transformer .05% accuracy.



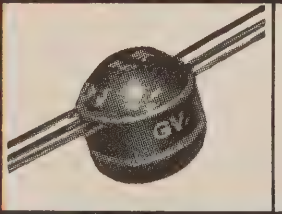
Multi-control magnetic amplifier for airborne servo.



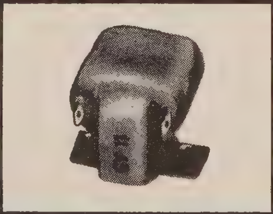
Input, output, two tune interstages, peaking ne work, and BP filter, all one case.

PULSE TRANSFORMERS

From miniature blocking oscillator to 10 megawatt.

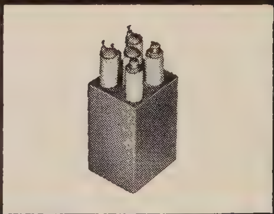


Wound core unit .01 microsecond rise time.



Pulse current tansformer 100 Amp.

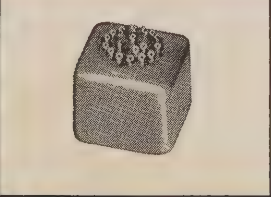
Pulse output to magnatron, bifilar filament.



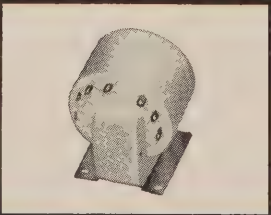
Precise wave shape pulse output, 2500 V. 3 Amps.

POWER COMPONENTS

Standard and high temperature . . . hermetic, molded, and encapsulated.

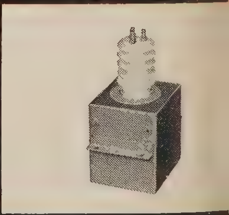


Multi-winding 140 VA, 6 KC power transformer 1¼ x 1¼ x 1″



200° C. power transformer, 400 ∼, 150 VA.

400 ∼ scope transformer, 20 KV output.



60 ∼ current limiting fil ment transformer, Sec. Mmfd., 30 KV hipot.

COVER

The advent of more powerful and sensitive radars has led to novel proposals for studying the surface of the moon by radar, as reported in the Correspondence section of this issue. Shown on the cover is a 142-foot steerable parabolic antenna, the second largest in the world, located in Fraserburgh, Scotland. Built and operated by Stanford Research Institute under contract with the Rome Air Development Center, this antenna was used in the moon radar experiments reported on page 932.

MOST RELIABLE "WRAP-AND-ENDFILL" FILM CAPACITORS—

Reliability in a "wrap-and-endfill" at last! . . . Sprague Yellow-Jacket Filmite "E" Capacitors. The design of these small, lightweight film capacitors is based on the most extensive life test data for polyester film dielectrics available at the present time. These capacitors will withstand a 250 hour accelerated life test of 150% of the 85 C rated voltage impressed or the equivalent derated 125 C voltage. *Not more than 1 failure is permitted in 25 samples tested.*

The "extended-foil" capacitor sections are fully protected against moisture by an outer wrap of yellow polyester-film tape. Only ultra-thin, specially selected foil and polyester film are used. The end seals are of a plastic resin which has been formulated to bond with the film wrap and the tinned leads so as to provide a secure seal.

TYPE 158P

YELLOW-JACKET® CAPACITORS

for military and industrial electronics

Because of their outstanding resistance to humidity, vibration, and shock, Type 158P Yellow-Jacket Capacitors are ideal for many military, computer, industrial control, and similar applications. They are particularly well-suited for potting or encapsulating in electronic sub-assemblies, filters, etc.

For complete engineering data on Military-Grade Yellow-Jacket Film Capacitors (Type 158P) write for Engineering Bulletin 2301. Data on Sprague's Commercial and Entertainment Grade Yellow-Jacket Capacitors (Types 148P and 149P) is given in Bulletin 2063A. Both bulletins are available from Technical Literature Section, Sprague Electric Company, 235 Marshall Street, North Adams, Massachusetts.

In this article, Robert L. Sleven of our Department of Applied Electronics discusses a branch type *directional* filter and some surprising results of a study program.

Directional Filters

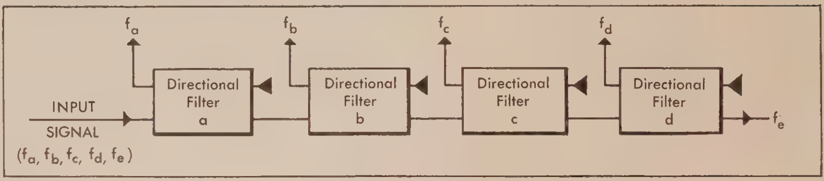

Figure 1. Directional Filter Multiplexer

The problem of "peeling off" the frequency components of an input signal as shown in Figure 1 is inherent in many countermeasures systems. While other types of filters have been used in the past, a rather unconventional filter appeared to offer several advantages. This filter (Figure 2) is a branch-type *directional* filter and its performance has recently been studied at AIL. The study program revealed the surprising result that many of the advantages of directional filters can be obtained if *one* and *only one* resonator is included in each branch.

The directional filter is a four-port network whose ideal responses are:

Port 1—Unity SWR
Port 1 to Port 2—
  Band-Pass Response
Port 1 to Port 3—
  Infinite Isolation
Port 1 to Port 4—
  Band-Reject Response

A network with the above performance is well-suited for multiplexing systems as can be seen from the block diagram shown in Figure 1. Signals at the resonant frequency of each directional filter will appear at the correct ports without any branching loss and the effect of one directional filter upon the other is negligible. This is not true with conventional branching filters.

The symmetry of the branch line directional filter is utilized to simplify the analysis of the four-port network by reducing it to an equivalent two-port. The overall network can be described as the product of three ABCD matrices. One of these matrices is for the filter network in each branch of the directional filter and the other two matrices are for lengths of transmission line corresponding to the spacing of the branches along the main transmission lines. In order to obtain theoretically the response stated above for each of the directional filter ports, certain conditions must be imposed on each of the matrices. High directivity (isolation of Port 3 from Port 1) is obtained when each branch of the directional filter is identical and the spacing of the branches is $(2n + 1)\ \lambda/4$ on one manifold and $(2n + 3)\ \lambda/4$ on the other manifold. To obtain the desired response at Ports 1, 2 and 4, conditions are imposed on the filter network which cannot be satisfied when each branch contains multiresonator filters. The filter network, in order to satisfy all conditions, must have identical driving point and transfer functions. This requirement can only be fulfilled when each branch of the directional filter contains one resonator. This result is significant because in the past it had been felt that as greater selectivity was required, more resonators would be used in each branch of the directional filter.

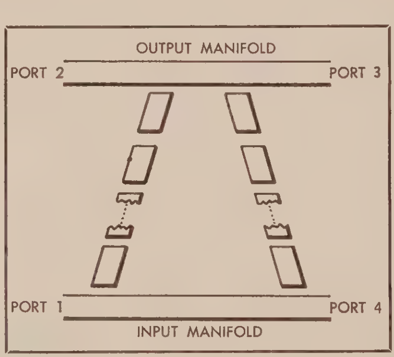

Figure 2. Branch Line Directional Filter

After having proved that ideal directional filter characteristics were not theoretically obtainable with multiresonator branches, the study continued until a suitable compromise in the response at each of the ports, was found, for the multiresonator case. The discrepancies between desired and obtainable directional filter performance differ depending upon the number of resonant elements in each branch. With an even number of dissipationless resonators in each branch, the power at resonance divides between Ports 2 and 4 and finite SWR exists at Port 1. With an odd number of resonant elements in each branch, the desired directional filter performance is obtained at resonance: that is, all power out Port 2. Except for the one resonator case, however, all directional filters with an odd number of resonators in each branch exhibit high SWR's at points in the passband.

The effect of dissipation on the directional filters performance is to mask some of the undesired characteristics and to magnify others. The passband SWR's are diminished in the presence of loss and the power out Port 4, which should be zero at resonance, becomes significant when dissipation is present.

The conclusions drawn from the directional filter study program were: (1) the ideal directional filter response listed above is theoretically obtainable when each branch consists of only one resonator and (2) when the selectivity of multiresonator filters is required, proper selection of filter decrements and coefficients of coupling will result in a directional filter response that is adequate for many purposes. The theoretical conclusions of the branch line directional filter program were verified experimentally by AIL.

A complete bound set of our fourth series of articles is available on request. Write to Harold Hechtman at AIL for your set.

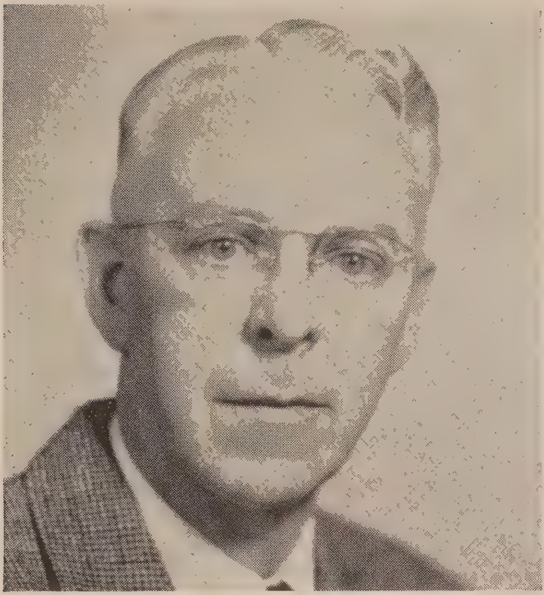
HAROLD S. BLACK, LAMME MEDALIST



1864 · BENJAMIN GARVER LAMME · 1924
"THE ENGINEER VIEWS HOPEFULLY THE HITHERTO UNATTAINABLE"

A MAN WINS A MEDAL...AND STRENGTHENS A PHILOSOPHY

The search for the "hitherto unattainable" sometimes ends in strange places.

For years Bell Laboratories engineer Harold S. Black pondered a problem: how to rid amplifiers of the distortion which unhappily accumulated as signal-transmission paths were made longer and amplifiers were added. There had been many approaches but all had failed to provide a practical answer.

Then one day in 1927 the answer came—not in a research laboratory, but as he traveled to work on the Lackawanna Ferry. On a newspaper, Mr. Black jotted down those first exciting calculations.

Years later, his *negative feedback principle* had revolutionized the art of signal amplification. It is a principal reason why telephone and TV networks can now blanket the country, the transoceanic cable is a reality, and military radar and missile-control systems are models of precision.

For this pioneer achievement, and for numerous other contributions to communications since then (some 60 U. S. patents are already credited to him), Mr. Black received the 1957 Lamme Medal from the American Institute of Electrical Engineers. He demonstrated that the seemingly "unattainable" often *can* be achieved, and thus strengthened a philosophy that is shared by all true researchers.

He is one of many Bell Telephone Laboratories scientists and engineers who have felt the challenge of telephony and have risen to it, ranging deeply into science and technology. Numerous medals and awards have thus been won. Two of these have been Nobel Prizes, a distinction without equal in any other industrial concern.

Much remains to be done. To create the communication systems of the future, we must probe deeper still for new knowledge of Nature's laws. We must continue to develop new techniques in switching, transmission and instrumentation for every kind of information-bearing signal. As never before, communications offer an inspiring challenge to creative men.

BELL TELEPHONE LABORATORIES
WORLD CENTER OF COMMUNICATIONS RESEARCH AND DEVELOPMENT

To assure a new order of reliability

MICRO-MODULE

EQUIPMENT

The micro-module is a new dimension in military electronics. It offers answers to the urgent and growing need for equipment which is smaller, lighter, more reliable and easier to maintain. Large scale automatic assembly will bring down the high cost of complex, military electronic equipment. Looking into the immediate future, we see a tactical digital computer occupying a space of less than two cubic feet. It will be capable of translating range, wind velocity, target position, barometric pressure, and other data into information for surface to surface missile firings. The soldier-technician monitoring the exchange of computer data will have modularized communications with the other elements of his tactical organization. RCA is the leader contractor of this important United States Army Signal Corps program and is working in close harmony with the electronic components industry.

Hermes Electronics Co.
CRYSTAL FILTER
10 MB
78

AEROTRON, 600 Series, Two-way VHF-FM Radio Communications Equipment

Hermes Crystal Filter, Model 10 MB, measures 2⅜" long x 1" wide x 1$\frac{1}{32}$" high.

The AEROTRON, Model 600 Series, is the first commercially available two-way VHF-FM Mobile Radio Equipment to use a high frequency crystal filter to guarantee Receiver selectivity for the life of the equipment. This equipment is designed by Aeronautical Electronics, Inc. of Raleigh, North Carolina, for the new "split channel" frequency allocations where exceptional frequency stability and selectivity are imperative. The use of a Hermes Crystal Filter at the highest intermediate frequency eliminates any desensitization from very strong, adjacent channel stations and offers a very flat response throughout the bandpass of the filter.

Hermes crystal filters were selected because of their superior performance, small size, and immediate availablity. Close cooperation between the engineering departments of the two companies contributed to the rapid development of this new Mobile Radio Equipment. Receiver characteristics include: *Frequency Stability:* ±0.0005% over −40 to +75°C; *Sensitivity:* 0.6 microvolt or less for 20 db quieting; *Selectivity:* ±7.5 kc at 6 db down; *Modulation Acceptance:* ±½ db throughout bandpass range of ±6 kc.

Whether your selectivity problems are in transmission or reception, AM or FM, mobile or fixed equipment, you can call on Hermes engineering specialists to assist you in the design of your circuitry and in the selection of filter characteristics best suited to your needs. *Write for Crystal Filter Bulletin.*

A limited number of opportunities are available to experienced circuit designers. Send résumé to Dr. D. I. Kosowsky.

Meetings with Exhibits

As a service both to Members and the industry, we will endeavor to record in this column each month those meetings of IRE, its sections and professional groups which include exhibits.

△

May 23-25, 1960

1960 National Telemetering Conference, Miramar Hotel, Santa Monica, Calif.

Exhibits: Mr. William Van Dyke, Douglas Aircraft Co., Inc., El Segundo, Calif.

May 24-26, 1960

Seventh Regional Technical Conference & Trade Show, Olympic Hotel, Seattle, Wash.

Exhibits: Mr. Rush Drake, 1806 Bush Place, Seattle 44, Wash.

May 24-26, 1960

Armed Forces Communications & Electronics Association Convention and Exhibit, Sheraton-Park Hotel, Washington, D.C.

Exhibits: Mr. William C. Copp, 72 West 45th St., New York 36, N.Y.

June 20-21, 1960

Chicago Spring Conference on Broadcast and Television Receivers, Graemere Hotel, Chicago, Ill.

Exhibits: Mr. Stanley Hopper, Zenith Radio Corp., 6001 W. Dickens Ave., Chicago 39, Ill.

June 27-29, 1960

National Convention on Military Electronics, Sheraton-Park Hotel, Washington, D.C.

Exhibits: Mr. L. David Whitelock, BuShips, Electronics Div., Dept. of Navy, Washington, D.C.

August 1-3, 1960

Fourth Global Communications Symposium, Hotel Statler, Washington, D.C.

Exhibits: Mr. Robert O. Brady, Office of the Chief Signal Officer, U. S. Army Signal Corps, Washington, D.C.

August 23-26, 1960

WESCON, Western Electronic Show and Convention, Ambassador Hotel & Memorial Sports Arena, Los Angeles, Calif.

Exhibits: Mr. Don Larson, WESCON, 1435 LaCienega Blvd., Los Angeles, Calif.

September 19-21, 1960

National Symposium on Space Electronics & Telemetry, Shoreham Hotel, Washington, D.C.

Exhibits: Mr. Leon King, Jansky and Bailey, 1339 Wisconsin Ave., N.W., Washington, D.C.

October 3-5, 1960

Sixth National Communications Symposium, Hotel Utica & Utica Municipal Auditorium, Utica, N.Y.

Exhibits: Mr. R. E. Bischoff, 19 Westminster Road, Utica, N.Y.

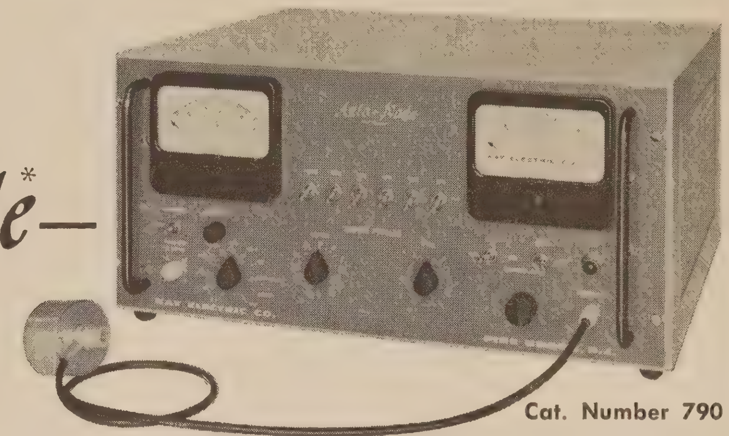
A Complete, Automatic Noise Figure Test Set

NEW!

KAY

—*Auto-Node**—

**AUTOMATIC
NOISE FIGURE TESTS
AND GAIN OR LOSS
MEASUREMENTS
AT UHF, VHF AND
MICROWAVE FREQUENCIES**



Cat. Number 790

- **Optimum Noise Figure Adjustments**
- **Precision Noise Figure Read Out**
- **Noise Figure Measurements using other type External Noise Generators**
- **Precision Measurements of Gain or Loss in components and systems at Microwave, UHF and VHF Frequencies**
- **No Errors Associated with Temperature-Limited-Diodes, Meter Readings, Transit Time**

SPECIFICATIONS

as an automatic noise-figure measuring set:

Useful Frequency Range of Noise Generator: 2-2000 mc.

Maximum VSWR Variation during test: 2 parts per 1000.

Noise Figure Accuracy Including Read Out Error:

$$\pm\ 0.1\ \text{db} \pm \frac{\text{Noise Figure}}{20}\ (\text{db})$$

(depends mainly on noise figure calibration of post amplifier).

Nominal Output Impedance of Noise Generator: 50 ohms (N-type connector).

Noise Figure Range: 0-18 db.

Input Center Frequency: 30, 60 or 70 megacycles (others available on special request).

Input Impedance: 70 ohms nominal.

Maximum Noise Figure of Measuring System: 3.5 db (matched) 2 db (mismatched).

Accuracy of System when making other type measurements including Microwave, UHF, and VHF Gain or Loss: ±0.2 db.

Power Requirements: 117V, 60 cps.

Dimensions: 9¾″ × 19½″ × 13″

Weight: 55 lbs. (approx.)

Price: $1,995.00, f.o.b. factory.

Kay Auto-Node is a complete, highly flexible, Automatic Noise Figure Test Set designed to obtain simplified, noise figure meter displays for making optimum noise figure adjustments and provide precision noise figure read-out, noise figure measurements using other type external noise generators as well as precision measurements of Gain or Loss in components and systems at microwave, UHF and VHF frequencies.

Kay Auto-Node Automatic Noise Figure Test Set features a small, probe size, temperature modulated resistor as a noise generator having the following additional characteristics.

- Sine wave temperature-modulation at a 10 cps rate with temperature excursions between 300° and 400° K
- Extremely small VSWR variations during modulation (less than 2 parts in 1000)
- Useful frequency range of noise generator from 2 to 2000 mc.

KAY Auto-Node's high-gain, low-noise post amplifier has excellent noise figure stability, better than 3.5 db (matched) and the gain is sufficient to raise the input noise to a value of 10 volts after final detection. The bandwidth is 2 megacycles and the unit is supplied with one of three center frequencies—30, 60 or 70 mc.

Kay Auto-Node's precision step attenuator and expanded output meter allows for measurements to within 0.2 db accuracy when making Gain or Loss measurements. Bridge detection and selective AGC, allows noise figure up to 18 db to be made with small temperature modulation in the noise source.

OTHER KAY NOISE GENERATORS

ACTUAL
SIZE

you can put 34,560 of these transformers in 1 cubic ft.!

We call these transformers "Red Specs." You probably wouldn't want to put 34,560 of them in a cubic foot, but you could if you had to. Actual dimensions are .310″ x .390″ base and .440″ high. Volume is .05 cu. in.

Designed for use with transistors, they are adaptable to printed circuit mounting or chassis wiring. Their wide frequency range, low distortion, and high efficiency add up to amazing performance in units of this size. Complete performance information is available if you will ask for the "Red Spec" pamphlet. Write today. Meanwhile, we list below a few of the thirty-six items available.

TYPE NO.	TYPE	PRIMARY	SECONDARY

No Down Time Is Normal . . .

Alfred Electronics Model 504 Microwave Amplifiers, in use at Hughes Aircraft Co., Culver City, California

*with **ALFRED** Microwave Amplifiers*

These Alfred TWT microwave amplifiers have seen continuous service at Hughes for over 9 months. There has been practically no down time even for replacement of TWT tubes. Used in the RF portion of a missile testing system, the Alfred units provide high gain, wide band, flat response and low spurious modulation from 8 to 12.4 kmc. Hughes engineers praise the functional layout of the Model 504, its simple operation and reliable performance.

In short, Hughes finds the Alfred 504 Microwave Amplifiers good, sound, straightforward reliable instruments. We think you will too.

KEY SPECIFICATIONS—ALFRED MICROWAVE AMPLIFIERS

	Model	Frequency Range kmc	Gain db (min)	Power Output (min)	Price
General Purpose Amplifiers for AM, Pulse and Phase Modulation	505	1 to 2	30 db	10 mw	$1,550
	501	2 to 4			$1,390
	503	4 to 8			$1,490
	504	8 to 12.4			$1,490
	549	10.5 to 16			$3,550
Medium Power Amplifiers	5-6752	1 to 2	30 db	1 w	$2,290
	512	2 to 4	30 db	1 w Pulsed	$1,850
			20 db	100 mw CW	
	502	2 to 4	30 db	1 w	$1,390
	5-6868	2 to 4	30 db	10 w	$2,850
	506	4 to 8 4.5 to 7.5	27 db	.5 w 1 w	$2,290
	5-542	4 to 8	25 db	1 w	$3,190
	510	8 to 12.4	20 db	100 mw	$2,150
	509	8.2 to 11	27 db	.5 w	$3,150
	5-6996	8 to 9.6	30 db	10 w	$3,590
High Power Amplifiers	5-6826	2 to 4	30 db	1 kw pk	$4,850
Low and Medium Noise Figure Amplifiers	Amplifiers with low and medium noise figures are available either as packaged units or unitized for remote operation of TW tube and solenoid. Standard units provide coverage from .5 to 12.4 kmc with noise figures from 7 db up.				

MANY MODELS TO CHOOSE FROM

The 504 is just one model from the industry's most complete line of microwave amplifiers. For technical details and a demonstration arranged at your convenience, contact your nearby Alfred representative or write direct. Please address . . .

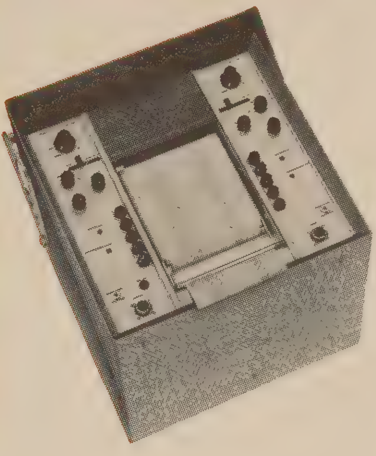
OF RESEARCH, DESIGN, TEST DATA

two channels



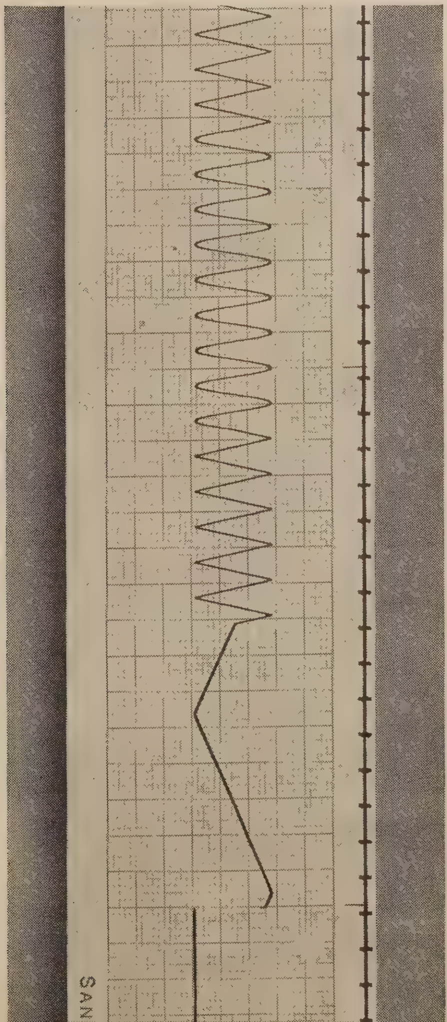
For General Purpose DC Recording — Model 320

For recording *two variables* simultaneously, the Model 320 provides a versatile, transistorized amplifier for each input signal. The rugged 2-channel recorder assembly has heated stylus recording on two *50 mm wide* rectangular coordinate channels, 4 pushbutton chart speeds, and 6 inches of visible chart. The Recorder can be placed vertically, horizontally or at a 20° angle.

MODEL 320 SPECIFICATIONS

Sensitivity: 0.5, 1, 2, 5, 10, 20 mv/mm and v/cm
Frequency Response: 3 db down at 125 cps, 10 mm peak-to-peak
Common Mode Voltage: ±500 volts max.
Common Mode Rejection: 140 db min. DC
Calibration: 10 mv internal ±1%
Output Connectors for each channel accept external monitoring 'scope or meter
Price: $1495

NEW SANBORN PORTABLE DIRECT WRITING RECORDERS FOR IN-PLANT, LABORATORY OR FIELD RECORDING



Two models of this 21 lb. brief case size recorder are available — Model 301 for AC strain gage recording, Model 299 for general purpose DC recording. Both provide immediately visible, inkless traces by heated stylus on 40 division rectangular coordinate charts . . . frequency response to 100 cps . . . 5 and 50 mm/sec chart speeds . . . approx. 4 inches of record visible in top panel window.

single channel

MODEL 301 SPECIFICATIONS

The amplifier section of the Model 301 is an all-transistorized carrier type with phase sensitive demodulator. The power supply and internal oscillator circuits are also transistorized.
Sensitivity: 10 uv rms/div (from transducer)
Attenuator Ratios: 2, 5, 10, 20, 50, 100, 200
Carrier Frequency: 2400 cps internal
Transducer Impedance: 100 ohms min.
Calibration: 40 uv/volt of excitation
Output Connector: for external monitoring 'scope or meter
Price: $750

MODEL 299 SPECIFICATIONS

Combines the dependability of transistors with the high input impedance of vacuum tubes for reliable broad-band DC recording.
Sensitivity: 10, 20, 50, 100, 200, 500 mv/div and 1, 2, 5 and 10 v/div
Input Resistance: 5 megohms balanced each side to ground
Common Mode Voltage: ±2.5 volts max. at 10 mv/div sensitivity increasing to ±500 volts max. at other sensitivities
Common Mode Rejection: 50:1 most sensitive range
Calibration: 0.2 volt internal ±1%
Output Connector: for external monitoring 'scope or meter
**Price: Model 299 (with zero suppression) $700
Model 299A (without zero suppression) $650**

All prices are F. O. B. Waltham, Mass., within continental U. S. A. and are subject to change without notice.

Contact your Sanborn Sales-Engineering representative for complete information, or write the main office in Waltham. Sales-Engineering representatives are located in principal cities throughout the United States, Canada and foreign countries.

BENELUX SECTION TO CONDUCT DATA TRANSMISSION SYMPOSIUM

The Benelux Section of the IRE has announced an International Symposium on Data Transmission, to be held at Delft, Netherlands, on September 19 and 20, 1960. The symposium will be concerned with the problems of transmitting and receiving information in digital form. Particular emphasis will be placed on the behavior of practical communication networks—including existing telephone systems, existing and planned military systems, and schemes of the future, such as those that use satellites. Appropriate topics include the choice of modulation, the application of coding, the demands of channel users, the design of new systems and the improvement of old, the behavior of links and networks under test, and the selection of models for further study. The aim will be to reduce the gap now existing between theory and practice.

The symposium will be conducted in English. Papers already promised indicate good representation of the work being carried on in the USA, as well as that conducted in Europe. The Symposium Committee consists of H. C. A. van Duuren, Chairman, B. B. Barrow, H. Rinia, and F. L. Stumpers. All correspondence regarding the symposium should be addressed to B. B. Barrow, Secretary, The Benelux Section of the IRE, Postbus 174, Den Haage, Nederland.

FIRST ARMY MARS NET PRESENTS MAY SPEAKERS

With the presentation of its May Speaker Schedule, the First U. S. Army MARS SSB Technical Net will recess its weekly series of technical talks and forum until September of this year. The Net meets on 4030 kc each Wednesday at 9:00 P.M. EDT. The schedule for May includes:

May 4	"Antenna Panel," W. Offutt, Engineering Manager; L. De Size, Group Leader and B. Woodward, Engineer—Airborne Instrument Labs, Inc., Melville, L. I., N. Y.
May 11	"Frequency Control," Dr. G. Winkler, Scientist USARDL, Fort Monmouth, N. J.
May 18	"Communication Electronic Needs of the Future," Dr. J. V. Harrington, Division Head, and Dr. B. Lax, M.I.T. Lincoln Lab., Lexington, Mass.
May 25	"Fundamentals of Oscillator Operation," R. W. Gunderson, Editor, Braille Technical Press, New York, N. Y.

NBS HEAD HONORED BY CIVIL SERVICE LEAGUE

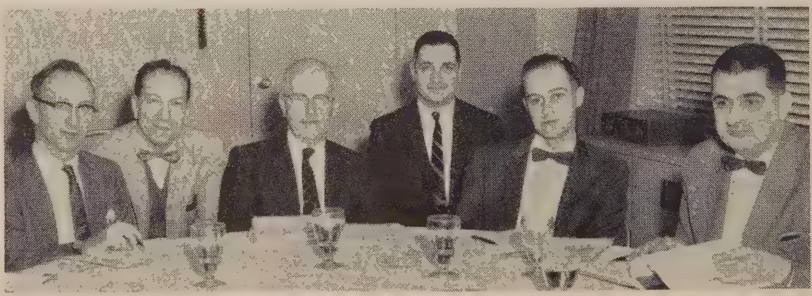
Allen V. Astin (SM'50–F'54), Director of the National Bureau of Standards, has been selected by the National Civil Service League as one of the top ten career employees in the Federal civil service for 1960. The Award was presented to Dr. Astin at a dinner in Washington, D. C., on March 15.

The League, a non-partisan citizens' organization for better government through better personnel, this year will give its sixth series of Career Service Awards to ten Federal employees chosen for competence, character and achievement.

Dr. Astin has been in government 27 years. A native of Salt Lake City, Utah, with degrees from the University of Utah, New York University, Lehigh and George Washington, he now lives in Bethesda, Md.

Joining the Bureau of Standards in 1932, he was active for eight years in research in the Heat and Power and Electricity Divisions, and during the next eight became successively Chief of the Optical Fuze Section and the Ordnance Development Division. He was promoted to Director of the Bureau in 1952.

Among his scientific contributions are the discovery and development of improved methods of measuring dielectric constants and power factors of dielectric materials; pioneering work in developing radio telemetering techniques and instruments, especially applied to meterological and cosmic ray problems; and contributions to the development and evaluation of proximity fuzes. His record of publications begins in 1929 and has continued productively. He has served on many committees and boards, such as the Defense Science Board, International Committee of Weights and Measures, and National Advisory Committee for Aero-



At a recent meeting of the national committee of the 13th Annual Conference on Electrical Techniques in Medicine and Biology, in the Sheraton Hotel, Philadelphia, Pa., where plans for the forthcoming Washington, D. C., conference (October 31, November 1–2) were made, *left to right:* A. L. Henley, secretary; Lewis Winner, public relations-exhibits; L. E. Flory, editorial board; A. Shapero, treasurer; G. N. Webb, program chairman and R. L. Bowman, conference chairman.

For unmatched reliability . . . BOMAC BEACON MAGNETRONS

Life — up to 500 hours guaranteed — over 3000 hours reported
Frequency stability — less than 2 Mc drift per 100 hours (C band)
Power stability — drop of less than 1 db for constant voltage input
Duty cycle stability — less than 3 Mc frequency shift for a change in duty cycle of 0.00005 to 0.002 (C band)
Vibration — less than 2.5 Mc frequency shift from 55 to 2000 cps
Shock — withstands 100 g's of 6 millisecond duration
Lightweight — 7 to 10 oz.
Miniaturized
Tunable over a broad band

nautics. He has had a leading role in government science programs and the direction of national and international science activities. His awards include the Presidential Certificate of Merit and His Majesty's Medal for Service in the Cause of Freedom.

NATIONAL SCIENCE FOUNDATION ESTABLISHES ADVISORY PANEL

A temporary Advisory Panel on Radio Telescopes has been appointed by the National Science Foundation. The purpose of the Panel is to 1) study the present and predictable needs of radio astronomers with regard to improved instrumentation; 2) study existing and proposed instruments with regard to their capabilities and limitations and 3) advise the Foundation with regard to the desirability and feasibility of more powerful instruments. The members of the Panel are Dr. J. R. Pierce, Bell Telephone Laboratories, Chairman; Dr. R. N. Bracewell, Stanford University; Dr. P. E. Chenea, Purdue University; Dr. L. J. Chu, Massachusetts Institute of Technology; Dr. R. M. Emberson, Assoc. Universities, Inc.; Dr. W. E. Gordon, Cornell University; Dr. D. S. Heeschen, National Radio Ast. Obs.; Dr. R. Minkowski, Mt. Wilson and Palomar Obs.; Dr. G. W. Swenson, Jr., University of Illinois; J. H. Trexler, Naval Research Lab. Scientists and engineers wishing to bring their ideas to the attention of the panel are encouraged to communicate them (to the panel members or directly) to the Astronomy Program, National Science Foundation.

CORNELL UNIVERSITY TO HOLD JUNE SEMINARS

The annual Industrial Engineering Seminars are being presented for the seventh successive year at Cornell University during June 14–17, 1960. Seminars will be conducted in seven major areas. Of these, those of interest to radio and electronics engineers will be the seminars in Engineering Administration, Systems Simulation Using Digital Computers, Statistical Decision-Making: Theory and Applications, and in Statistical Reliability Analysis: Theory and Applications.

The seminar series on Engineering Administration has been planned for persons responsible for the administration of engineering and applied research activities. Topics to be discussed include a) communication problems in the technical organization, b) manpower planning and the growing shortage of engineers, c) the development of engineers as supervisors, d) creativity through group effort, e) directing engineering programs, f) engineering program planning, g) the management of technical services, and h) cost control of engineering projects.

The seminar group on Statistical Reliability Analysis: Theory and Application will provide a current survey of statistical theory and techniques on reliability analysis that are being developed to meet the growing demands for improved materials and component reliability. It is intended for those engineers and manufacturing executives whose responsibilities include predicting and implementing the economic balance of product quality against cost through environmental destruction tests, marginal checking and failure analysis. Among the topics to be discussed will be: a) statistical aspects of experimentation, b) statistical theory of reliability based on failure models such as the exponential, Weibull, gamma and extreme-value, c) techniques of analyzing failure data, d) the improvement of reliability through redundancy and maintenance, e) the design of life-testing experiments, f) selection and ranking problems, and g) unsolved problems in reliability.

The use of simulated experimentation in the analysis and design of complex systems is one of the most promising of the applications of high-speed digital computers. The series of seminar sessions on Systems Simulation Using Digital Computers will explore this expanding field and consider problems in constructing the program, in using a simulator and in analyzing results. The topics for discussion will include a) the experimental investigation of complex systems, b) equipment requirements for digital simulation, c) the logical representation of an operating system, d) the construction of a computer program to simulate a simple system, e) problems in the design of a simulation experiment, f) experimental determination of

In preparation for the 1960 IRE 7th Regional Conference, Dr. D. K. Reynolds, Technical Program Chairman (*far right*) explains to other IRE committee chairmen the three major fields which the conference attendants will study. The conference, to be held in Seattle on May 24–26, will feature studies of control systems, solid state electronics, and electromagnetics. The other IRE conference chairmen include (*left to right*) W. T. Harrold, Public Relations Chairman; Rush Drake, Electronics Exhibit Chairman; Dr. Frank S. Holman, Chairman; L. C. Perkins, Chairman of the Seattle Section; and Frank A. Little, Treasurer.

LFE

is experienced ...in Radar Surveillance Systems

The eye was man's first instrument of surveillance. Its most unique characteristic is the ability to distinguish moving objects.

LFE, a pioneer in motion detection by radar means, is prime contractor for a new Ground Control Approach System for tactical air traffic control. Now in production, it exemplifies the latest in lightweight, portable GCA equipment.

This is an illustration of LFE's interest in radar techniques with continued emphasis on motion detection. Such techniques are having an evolutionary influence on military and industrial systems.

Further details about LFE Radar Surveillance Systems may be had by writing the Vice President of Marketing. Ask for Technical Data Digest No. 6025.

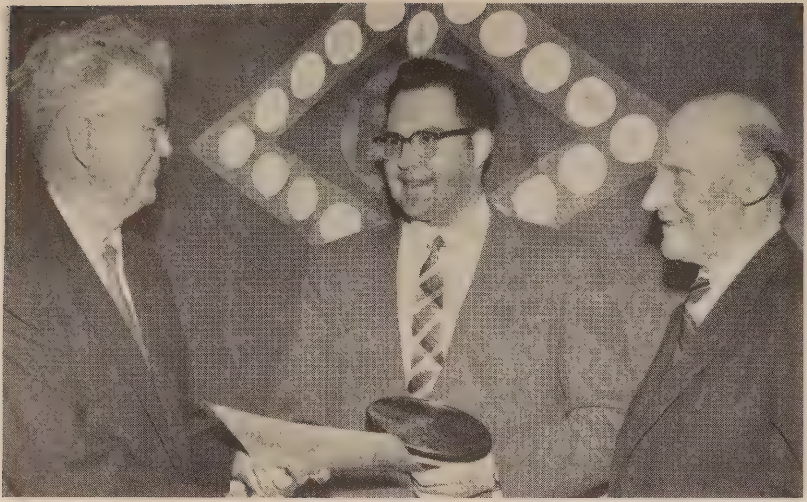
SYSTEMS, EQUIPMENT & COMPONENTS FOR

AIRBORNE NAVIGATION • RADAR and SURVEILLANCE • ELECTRONIC DATA PROCESSING • AUTOMATIC CONTROLS • GROUND SUPPORT



Dr. Edgar A. Sack, Jr. (*center*), who received recognition by Eta Kappa Nu as the outstanding young electrica engineer of 1959, receives congratulations from HKN's President, Albrecht Naeter (*left*) and Dr. Ernst Weber, president of Brooklyn Polytechnic Institute, who delivered the major address of the evening.

optimum operating conditions, g) production control simulation and the comparison of decision rules, and h) manufacturing systems simulation.

The seminar on Statistical Decision-Making is designed for individuals who are engaged in research, experimentation, production, inspection, or acceptance sampling where attention is centered on problems of selecting or ranking processes, methods, or categories according to various criteria of "goodness." It will consist of integrated sessions in which new statistical procedures will be proposed for coping with such multi-decision problems. Among the topics to be discussed will be a) some statistical aspects of experimentation, b) multiple comparison procedures: why and how they are used, c) three-decision problems, d) selection and ranking problems (Bechhofer-Sobel approach), e) selection and ranking problems (Sommerville approach), f) selection and ranking problems (Gupta-Sobel approach), and g) implications of the approaches, directions of research, and new applications.

These seminars are sponsored by the Department of Industrial and Engineering Administration of the Sibley School of Mechanical Engineering, College of Engineering at Cornell. For further information address inquiries to: J. W. Gavett, Seminars Coordinator, Upson Hall, Cornell University, Ithaca, N. Y.

PGPT Calls for Papers

The 4th Annual Conference of the PGPT will be held in Boston, Mass., on November 15–16, in conjunction with the 1960 Northeast Electronics Research and Engineering Meeting (NEREM). Papers for two sessions, to be grouped under the general headings of "Design Techniques That Insure a Better Product," and "Materials and the Product Today," are being solicited. Reports on new and original work in these fields are especially desired. Prospective authors should submit, before June 1, 1960, summaries of their papers, in triplicate, to C. W. Watt, Program Chairman, 4th Annual Conference PGPT, c/o Raytheon Company, Waltham 54, Mass.

Marquette University To Sponsor Institute

An Institute sponsored by the Department of Electrical Engineering of Marquette University will be held on June 1 and 2, 1960. The title of the Institute is "Recent Advances in Solid State Devices." The program emphasizes High-Power Controlled Rectifiers, Application of the Silicon Controlled Rectifier, Parametric Amplification, Tunnel Diode and Applications, Direct Energy Conversion—Thermoelectric Devices, Direct Energy Conversion, Solid State Maser Amplifiers, Avalanche Devices and Solid State "Grown" Circuits. Persons highly specialized in their fields will present the program.

For further information write to Stanley Krupnik, Jr., Assistant Chairman of Electrical Engineering, Marquette University, Milwaukee 3, Wis.

PGRFI Will Conduct 2nd Annual Symposium

The Professional Group on Radio Frequency Interference (PGRFI) will hold its 2nd Annual Symposium in Washington, D. C. at the Shoreham Hotel on June 13 and 14, 1960.

The program will include morning and afternoon sessions on both Monday, June 13 and Tuesday, June 14. The morning session on June 13 will deal with RFI prediction with various computer models, the afternoon program with measurement methods and system characteristics. A total of 10 papers will be presented. The second day will feature a round table discussion in the morning covering the present status of RFI and compatibility standards. In the afternoon, there will be a field trip to the NOL and FCC Laboratories. The ladies' program will include a daily hospitality room, a fashion show, an embassy tea, and a sightseeing tour.

Advance registration is recommended; for further information please contact: E. F. Mischler, Chairman, Public Relations Committee, National Engineering Service, 1108 16th Street, N.W., Washington 6, D.C.

Summer Workshop Announced

A day and a half tutorial program on solid-state electronics is to be presented at Purdue University on June 23 and 24, 1960 under the joint sponsorship of the IRE Professional Group on Education and the Electrical Engineering Division of ASEE. The program for the event was announced by Dr. John G. Truxal and Dr. J. H. Mulligan, Jr., respective Chairmen of the two organizations. Dr. Warren B. Boast, Iowa State University, is Chairman of the Program Committee for the Workshop. Other members are Dr. R. H. Mattson, Iowa State University; Dr. J. L. Moll, Stanford University; Dr. R. L. Pritchard, Texas Instruments, Inc., and Mr. G. R. Madland, Motorola Semiconductor Products Division.

Designed primarily for electrical engineering educators, but open to all interested parties, the Workshop will include nine papers arranged in three sessions as follows:

Thursday afternoon, June 23

"Characteristics of Electrons in Solids," *Dr. J. M. Shive, Bell Telephone Lab., Inc.*

"Semiconductors," *Dr. R. H. Mattson, Iowa State University.*

"Electrical Properties of Semiconductor Materials," *Dr. W. G. Dow, University of Michigan.*

Friday morning, June, 24

"Diodes," *Dr. M. O. Thurston, Ohio State University.*

"Transistors," *Dr. J. M. Early, Bell Telephone Lab., Inc.*

Friday afternoon, June 24

"Energy Conversion Devices," *Dr. S. J. Angello, Westinghouse Electric Corp.*

"Low Temperature Devices," *Dr. A. L. McWhorter, Lincoln Labs., M.I.T.*

"Other Solid State Devices," *Dr. J. L. Moll, Stanford University.*

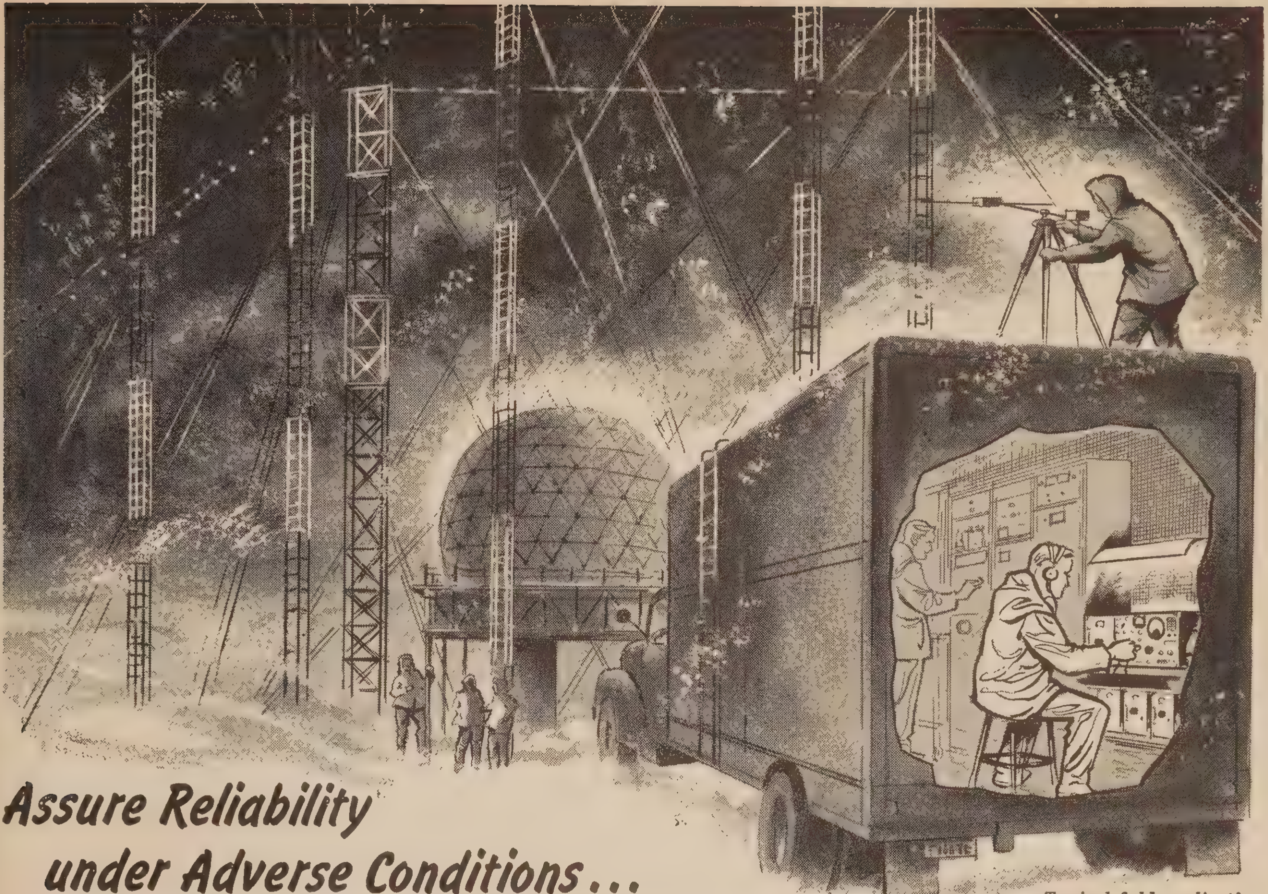
Further details regarding program information may be obtained from Dr. Warren B. Boast, Iowa State University, Ames, Iowa; information regarding living accommodations for the meeting may be obtained from Dr. Thomas F. Jones, Purdue University, Lafayette, Ind.

The Workshop on Solid-State Electronics is but one of the events of the Electrical Engineering Division scheduled for the ASEE Annual Meeting at Purdue University. On Monday, June 20 there will be a session on "Learning Machines" under the chairmanship of Professor A. V. Eastman of the University of Washington. The following papers will be presented:

"The Automization of Socrates," *Dr. D. Cook, Purdue University.*

"Design Techniques of Automatic Teaching Machines," *Dr. H. A. Baldwin, University of Arizona.*

"Teaching Elementary Stress Analysis



Assure Reliability under Adverse Conditions...

Typical field application of NF-105 in mobile Radio Interference Laboratory

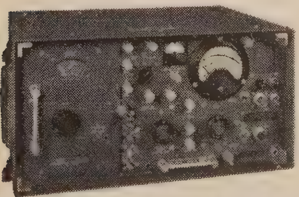
SPECIFY EMPIRE'S COMPACT AND RUGGED

NOISE and FIELD INTENSITY METER

MODEL NF-105

- Measures 150 kilocycles to 1000 megacycles accurately and quickly with only one instrument.
- For measurements in accordance with Specifications: MIL-I-6181B, Class 1; MIL-S-10379A; MIL-I-11683B; MIL-I-11748B; MIL-I-12348A; MIL-I-13237; MIL-I-16910A; MIL-I-26600 (USAF), Category A; F.C.C. Specifications.
- Direct substitution measurements by means of broad-band impulse calibrator, without charts, assure repeatability.
- Economical...avoids duplication.
- True peak indication by direct meter reading or aural slideback.
- Four interchangeable plug-in tuning units, for extreme flexibility.
- Safeguards personnel...ALL antennas can be remotely located from the instrument without affecting performance.
- Self-calibrating, for reliability and speed of operation.
- Compact, built-in regulated "A" and "B" power supply, for stability.
- Minimum of maintenance required, proven by years of field experience.

DELIVERY FROM STOCK



The unique design of Model NF-105, with 4 plug-in tuning units, avoids costly repetition of circuitry and components common to all frequency ranges, at savings in size, weight and cost. Simple to operate, this instrument permits fast and accurate measurements of both broadband or CW signals. *Send for our Catalog N-604.*

Plan to attend our next seminar on interference instrumentation, details upon request.

On Monday evening at 8:00 P.M. there will be a panel discussion on the theme "The Role of the Electrical Engineering Division in the Next Decade." Participants will be Dr. Warren B. Boast, Head, Electrical Engineering Department, Iowa State University; Dr. Richard K. Moore, Head, Electrical Engineering Department, University of New Mexico; and Dr. James H. Mulligan. Jr., Head, Electrical Engineering Department, New York University.

On Tuesday, June 21 at 2:00 P.M. there will be a session devoted to Probability and Statistics in Electrical Engineering under the direction of Dr. J. Stuart Johnson, Dean of Engineering, Wayne State University. The four papers scheduled for this meeting are:

"Mathematics Approach to Probability and Statistics Instruction for Electrical Engineers," *Dr. J. G. Brainerd, University of Pennsylvania.*

"Electrical Engineering Approach to Probability and Statistics Instruction for Electrical Engineers," *Dr. R. J. Schwarz, Columbia University.*

"Random Process Studies and Information Theory," *Dr. V. C. Rideout and Dr. A. Burr, University of Wisconsin.*

"Reliability of Electronic Equipment," *Dr. C. A. Krohn, Motorola, Inc.*

PHOTOGRAPHY SEMINAR TO BE HELD AT M.I.T.

The scientific and engineering uses of high-speed photographic measurement techniques will be the subject of a one week seminar at the Massachusetts Institute of Technology, starting Monday, August 15, 1960. The meetings will center at the Stroboscopic Light Laboratory where the theory and application of numerous methods will be discussed and studied.

It is planned that mornings will be devoted to theory and demonstrations and the afternoons to laboratory practice and experience.

Subjects to be covered include pulsed stroboscopic lighting, optical high-speed cameras, Kerr cells, Faraday shutters, image converters, and so forth. Specialists in high-speed photography have been invited to cover their subjects at the seminar, and there will be practical laboratory demonstrations of many types of high-speed photography equipment.

The high-speed motion picture and still cameras give space-time resolution for complicated mechanical motions. In some ways one can think of high-speed cameras as instruments for the mechanical engineer that correspond to the cathode-ray oscillograph for the electrical. One of the objects of the seminar is to give those who attend a real working knowledge of the various devices.

The program is under the direction of Professor Harold E. Edgerton of the Department of Electrical Engineering at M.I.T. For further information inquire from the Office of the Summer Session, Room, 7-103, M.I.T., Cambridge 39, Mass.

AVAILABLE NOW FROM TI

100:1 miniaturization with SOLID CIRCUIT* semiconductor networks

Now — 3 years ahead of industry's expectations — *Solid Circuit* semiconductor networks from Texas Instruments for many of your high-reliability miniaturized systems!

Solid Circuit networks are a major departure from conventional components because they integrate resistor, capacitor, diode, and transistor functions into a single high-purity semiconductor wafer. Protection and packaging of discrete elements is eliminated, and contacts between dissimilar materials are minimized, reducing element interconnections as much as 80%. Fabrication steps have been reduced to one-tenth those required for the same circuit function using conventional components.

Only a few process steps and time-proved TI mesa production techniques permit a high degree of process control in *Solid Circuit* network fabrication. The result of these facts: *reliability is built into* each *Solid Circuit* network.

If you need to reduce equipment size and weight — or to design a more complex system in the same size — investigate *Solid Circuit* networks for your missile, satellite, space vehicle, and other microelectronic programs. TI engineers are ready to custom design this concept to your requirements. Contact your nearest TI Sales Engineer today. The TI Type 502 *Solid Circuit* network is immediately available for your evaluation.

SEMICONDUCTOR NETWORK CONCEPT

The concept of a semiconductor network is the relation of conductance paths in a semiconductor to the classical circuit elements, establishing an orderly design approach based on circuit knowledge. In this manner, semiconductor networks may be designed to perform the functions of a wide variety of existing circuits. Through the proper selection and shaping of semiconductor conductance paths, it is possible to realize such electronic functions as amplification, pulse formation, switching, attenuation, and rectification.

An assembly of 13 **Solid Circuit** networks, actual size, performs a full serial adder function, replacing 85 conventional components with a 100:1 size reduction. Weight: 1.5 gm. Volume: 0.02 cubic inch.

*Trademark of TEXAS INSTRUMENTS INCORPORATED

TI Type 502 silicon **Solid Circuit** network is intended for binary counter, flip-flop, or shift register applications. The dimensions of the glass-to-metal hermetic-sealed package are 0.250 x 0.120 x 0.030 inch.

Three members of the Washington, D. C., Section received Patron Awards for "distinguished service" to the Section at the Annual Banquet on February 13, 1960. *Left to right:* Stuart L. Bailey, President, Jansky and Bailey; Leland D. Whitelock, Head Engineer, Communications Branch, Bureau of Ships, Navy Department; John Durkovic, Chairman, Washington Section; Frencis H. Engel, Assistant to the Vice President, RCA Defense Electronics; and Dr. Ronald L. MacFarlan, IRE President, 1960.

RECORD ATTENDANCE AT 1960 SOLID-STATE CIRCUITS CONFERENCE

Over 3000 attended the recent 1960 International Solid-State Circuits Conference which was held on the campus of the University of Pennsylvania and at the Sheraton Hotel in Philadelphia, Pa.

Among those in attendance were scores of solid-state specialists from abroad—Japan, Italy, France, Sweden, Hungary, Switzerland, England and the Netherlands.

Honored guests included Leo Esaki of tunnel-diode fame; M. J. O. Strutt, chairman, Electrical Engineering Department, Swiss Federal Institute of Technology, and C. Guy Suits, Vice President and Director of Research, General Electric Company, the latter delivering invited addresses at the formal opening of the meeting.

A tribute was paid to the late Dudley Buck during an afternoon memorial session.

A complete conference report—100-page-letterpress-book with over 300 illustrations—covering the 43 papers presented, was distributed to all registrants. Post-conference copies of this text, officially known as the Digest of Technical Papers, are available from Henry G. Sparks, Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia 4, Pa., at $5.00 per copy. Remittance to be made out to "Solid-State Circuits Conference."

PURDUE UNIVERSITY TO HOST ANNUAL CONVENTION ON ENGINEERING EDUCATION

The fact that engineering education is currently in a state of change is reflected in the program which the American Society for Engineering Education has planned for its 68th annual convention at Purdue University June 20 through 24, 1960.

This largest and most significant meeting of the year, between educators and the engineers and employers of engineers in industry, will begin with an address by President Frederick L. Hovde of Purdue on his philosophy of the total education of the engineer. Some 45 general sessions and special conferences will follow during the week, in addition to numerous luncheons, dinners, and entertainment features.

Sessions will be held on "Methods of Teaching Electrical Engineering," "The Impact of Digital Computers on Engineering Education," and the EE and IRE Divisions will hold an extended workshop on "Solid State Electronics."

Of special note will be a general session by the Relations With Industry Division on Wednesday, June 22, on "Long Range Education and Development of the Engineer." Addresses will be given by Dr. Carl W. Borgmann, of the Ford Foundation; P. E. Haggerty, president of the Texas Instrument Company; Will Mitchell, Jr., associate research director of Allis Chalmers; and E. C. Koerper, consulting engineer.

A joint session by the Aeronautical Engineering, Mathematics and Physics Divisions will have as its theme "The Impact of New Technologies."

The currently live topic of high school preparation for college will be the subject of a major session to be presided over by Dr. A. R. Spalding, head of the Purdue department of freshman engineering, which receives some 2000 freshmen from secondary schools each year.

The Mechanics Division will feature a critical examination of "Substance and Objectives of Typical Curricula in Engineering Mechanics, Engineering Science, and Engineering Physics" by a panel consisting of Dr. Fred Lindvall, chairman of engineering at California Institute of Technology; Dr. Paul Chenea, head of the School of Mechanical Engineering at Purdue; Dr. J. H. Meier of General Electric; and Dr. Charles E. Taylor, of the University of Illinois.

Other major topics include "An Evaluation of Cooperative Education," "A National Survey of Technical Institute Education," and "The Future of Industrial Engineering."

For reservations and a complete program, address Prof. Mark Roberts, Engineering Administration, Purdue University, Lafayette, Ind.

TELEMETERING CONFERENCE PROGRAM COMPLETED

The 1960 National Telemetering Conference will be held May 23–25, 1960 at the new Miramar Hotel in Santa Monica, Calif. The theme of this year's conference is "Telemetry—Tool for Industry and Defense." Sponsoring societies are the Instrument Society of America (ISA) which is the 1960 host, the American Rocket Society (ARS), the American Institute of Electrical Engineers (AIEE), the Institute of Aeronautical Sciences (IAS), and the Institute of Radio Engineers (IRE).

Seventy-one technical papers have been selected, and will be presented in panel form in 16 separate sessions running 3 sessions concurrently. In addition, two workshop sessions are scheduled. Session topics are:

Monday Morning, May 23

"Industrial Data Transmission Systems"
"Bio-Medical Measurements"
"Space Data Acquisiton Systems"

Monday Afternoon

"General RF Components and Techniques"
Missiles and Aircraft Telemetry Workshop—
"R&D Needed in the 60's"
"Data Processing and Presentation"—I

Tuesday Morning, May 24

"PCM Progress"
"General—Transducers"
"Ground Stations—New Components and Techniques"

Tuesday Afternoon

"Industrial Supervisory Control"
"Missiles and Aircraft—Flight Data Systems"
"Telemetry Techniques"—I

Wednesday Morning, May 25

"Data Processing and Presentation"—II
"Missiles and Aircraft—Environment Measurement"
"General Transistorization Progress"

Wednesday Afternoon

Industrial Telemetry Workshop—"What We Really Need Is . . . "
"Telemetry Techniques"—II
"Reliability in Telemetry"

The latest in telemetry equipment and techniques will be displayed by leading manmanufacturers for both commercial industry and the military. Over 66 exhibit booth spaces have been provided in a layout in two large halls which are near to the technical sessions. In addition to the banquet and cocktail party, several interesting tours are planned for both conferees and wives.

Additional information may be obtained by contacting the Conference Chairman, Hugh Pruss, 8345 Hayvenhurst Ave., Sepulveda, Calif.

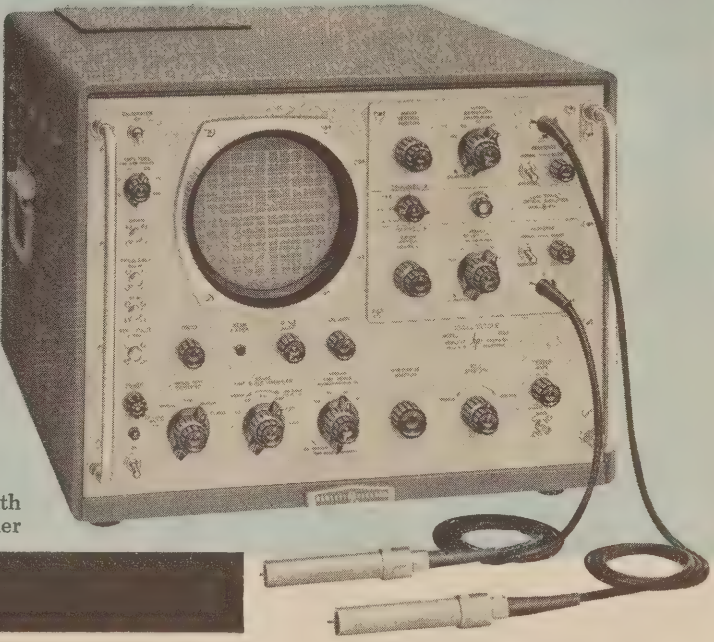
NEREM CALLS FOR PAPERS

Technical papers describing significant original contributions—focused on research

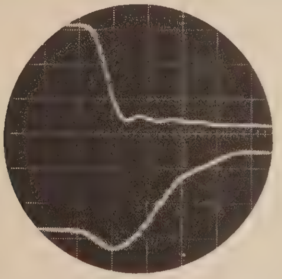
USE THIS NEW hp 185A 500 MC oscilloscope

now for these important measurements:

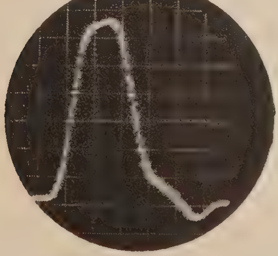
- Analyze millimicrosecond pulses
- Measure transistor response time
- Make fractional millimicrosecond time comparisons
- Measure diode switching time
- Determine pulse jitter
- Make permanent X-Y plots
- Measure memory-unit switching
- Measure uhf voltage amplitude



hp 185A Sampling Oscilloscope with
hp 187A Dual Trace Amplifier



Bright, clear dual pulse presentation on -*hp*- 185A's big 5″ scope face. Top trace shows pulse from mercury pulser applied to 2N1385 mesa transistor. Bottom trace shows responding turn-on of transistor. Dip in bottom trace at start of turn-on results from capacitance. Scope sweep speed is 1 mμsec/cm.



Brilliant, steady trace of a 2 millimicrosecond pulse on the 185A 5AQP cathode ray tube face.

6362

IMPORTANT FEATURES: Less than 0.7 mμsec rise time. 500 MC pass band; bright steady traces even at rep rates down to 50 cps. Sensitivity 10 mv/cm to 200 mv/cm; vernier increases sensitivity to 3 mv/cm. Sweep times 10 mμsec/cm to 100 mμsec/cm with expander to 0.1 mμsec. Front panel delayed sync pulse for triggering circuits under test. Dual channel input. 10 cm vertical display. High sensitivity, wide dynamic range. 100,000 ohm probe minimizes circuit disturbance. X-Y recorder output. Time-amplitude calibrators, beam finder, panel similar to conventional scopes. Built-in time and amplitude calibrators.

FOR COMPLETE DETAILS of this totally new, easy-to-use instrument, call your hp representative or write direct.

hp 185A 500 MC Oscilloscope, $2,000.00
hp 187A Dual Trace (plug-in) Amplifier, $1,000.00

hp *over 300 fast, accurate measuring instruments* and development—are invited for presentation at the 1960 Northeast Electronics Research and Engineering Meeting (NEREM) which will be held on November 15, 16, 17, 1960, in the Commonwealth Armory and the Sheraton-Plaza Hotel, Boston, Mass.

This year's meeting will project a marked departure in technical program format, scope and size, as well as type and number of exhibits. The program will feature many invited state-of-the-art tutorial sessions, with related evening informal discussion periods.

All registrants will receive, free-of-additional charge, a copy of the NEREM Record, a printed 200-page conference report with 600–1000 word digests (supported by drawings and photographs) of every paper presented at the meeting. Illustrated profiles of every NEREM speaker will also be included in the Record.

A suggestive, but not inclusive, list of subject areas for NEREM 1960 is: Antennas; Circuit Theory; Components, Production Techniques and Reliability; Electronic Computers; Engineering Management; Feedback Control Systems; Information Theory and Processing; Biomedical Electronics; Microwave Devices—Theory and Techniques—Involving Ferrites, Masers, Parametric Amplifiers and Ionized Media; Military Electronics Including Inertial, Infrared and Data-Handling Systems; Semiconductor Devices and Circuits Including Micro-Circuitry and Photo Electronic Applications.

To permit the development of well-integrated technical sessions, speakers are requested to furnish either complete papers or 400–500 word abstracts, in triplicate, plus 50-word summaries for advance program mailings.

All material should be mailed on or before July 15, 1960 to the 1960 NEREM Program Chairman, J. H. Mulligan, Jr., Dept. of Electrical Engineering, New York University, New York 53, N. Y. Authors will be notified of paper acceptance or rejection by August 15, 1960.

1922 receiver demonstrated at IRE Section Annual Banquet—The operation of the "Aeriola Sr. Receiver," a Westinghouse Product, is demonstrated by Captain W. F. Kirlin, Chairman of the Northwest Florida Section of the IRE, to Dr. R. L. McFarlan, International President of the IRE, and General R. H. Warren, Vice Commander, APGC. Ralph Coe, (left) Section Vice-Chairman, and Harold Hufnagle (right), Section Secretary-Treasurer, look on.

May Schedule Planned By Air Force MARS

The following is the schedule of the Air Force MARS Eastern Technical Net (3295 kc, 7540 kc, and 15,715 kc, on Sundays from 2 to 4 P.M. EST):

May 1 "Quality Control Techniques," A. Stein, Statistical Engineer, Riverside Plastics Corp.

May 8 "Medical Electronics in Gastro-Intestinal Research," Dr. J. T. Farrar, Chief, Gastro-Neurology Section of the Veterans' Hospital of New York and R. Bostrom, Research Engineer, Airborne Instruments Lab.

May 15 "The Evolution of Modern Radar," Dr. N. J. Nilsson, Chief, Directorate of Control and Guidance, Advanced Developments Lab., Rome Air Development Center, USAF.

May 22 "Air Crew Escape Systems," Discussion by engineers from Frankford Arsenal, USA.

May 29 "Materials," Discussion by engineers from Frankford Arsenal, USA.

1960 IRE 7th Region Conference

OLYMPIC HOTEL, SEATTLE WASH., MAY 24–26, 1960

The cocktail party, to be held May 24 in the Olympic Hotel, Seattle, Wash., is the traditional opening of the IRE 7th Regional Conference. The All-Industry Luncheon will also be held on May 24, in the Spanish Ballroom of the Olympic Hotel.

On May 25 a field trip will be conducted to the Transport Division of the Boeing Airplane Company, Renton, Wash. This will provide views of the following: the factory, flight line (radar test), electronic shops (radar checkout), electronic mock-up landing simulator, computer—IBM 704 (evaluation of flight situations), and airplane mock-up, both present and future.

Women's activities, under the direction of Mrs. Frank S. Holman, will include a reception and several cruises and excursions to interesting sites in the area.

Session 1—Opening General Session

Tuesday Morning, May 24

Chairman: *O. G. Villard, Jr., Stanford Univ., Stanford, Calif.*

Speakers: *F. S. Holman, Chairman, 7th Region Conference, Boeing Airplane Co., Seattle, Wash.; R. L. McFarlan, President, IRE; R. N. Clark, Univ. of Washington, Seattle; O. G. Villard, Jr., Stanford Univ., Stanford, Calif.*

Session 2

Control Systems I—Performance Criteria

Tuesday Afternoon

Chairman: *G. F. Franklin, Stanford Univ., Stanford, Calif.*

Co-Chairman: *F. C. Fickeisen, Boeing Airplane Co., Seattle, Wash.*

"Optimum Performance Criteria with a Minimum Lead System," *G. S. Axelby. Westinghouse Corp., Baltimore, Md.*

"Consideration in the Design of Feedback Control Systems with Optimum Performance," *R. L. Cosgriff and E. J. Hagin, Ohio State Univ., Columbus.*

"Optimum Control System with Minimum Spectral Bandwidth," *J. C. Hung, New York Univ., New York, N. Y.*

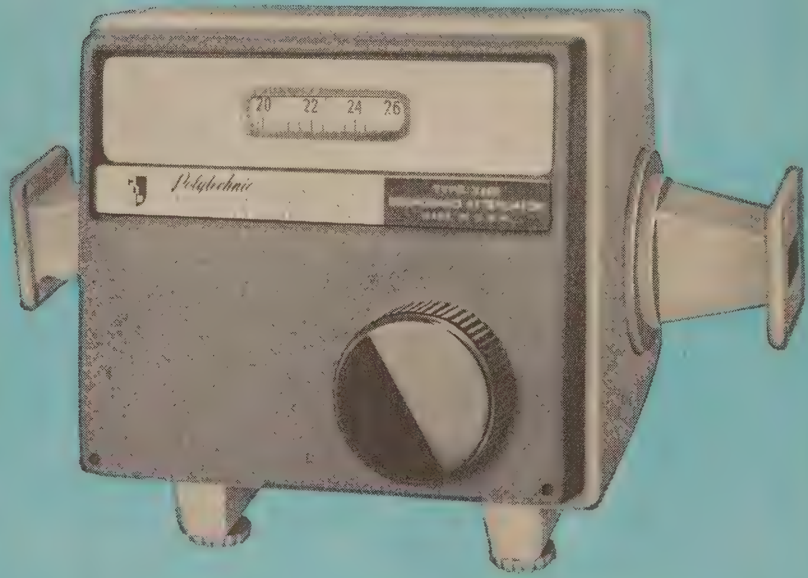
"Performance Measures—Past, Present, and Future," *W. C. Schultz, Cornell Aero Lab., Buffalo, N. Y., and V. C. Rideout, Univ. of Wisconsin, Madison.*

Session 3

Solid State Electronics I—Semiconductors

"Negative Resistance Processes in Semiconductors," *R. E. Burgess, University of*

PRD's brand new Broadband Attenuators



FEATURES:

- Short insertion length
- Full *60 db* attenuation range
- *Minimum* insertion loss
- Compact Tape readout
- Precision accuracy

Once again, to meet the present and future needs of microwave engineers, PRD has produced a completely new concept in test equipment. Here is a *rotary vane attenuator* in a radically modern package: small, light, rugged ...and *precise*—to fill all your needs from 3.95 to 40 kmc. The 101 series of Broadband Attenuators features a precise, compact, low-backlash drive and easy-to-read tape readout. Levelling screws quickly adjust to match transmission line heights. A simple adapter is available for panel mounting.

SPECIFICATIONS:

VSWR: 1.15 maximum

Attenuation Range: 60 db

Accuracy: ±0.1 db or ±2%, whichever is greater, from 0 to 50 db; ±3% from 50 to 60 db.

The table below indicates maximum insertion loss and dimensions.

Type No.	Freq. Range	Max. Insertion Loss	Insertion Length	Height	Depth
G 101	3.95 — 5.85	0.5 db	18⅞	6 5/16	7 3/16
C 101	5.3 — 8.2	0.5 db	14 7/16	6 5/16	7 3/16
H 101	7.05 — 10.0	0.5 db	11⅜	6 5/16	7 3/16
X 101	8.2 — 12.4	0.5 db	9	6⅛	6¼
U 101	12.4 — 18.0	0.7 db	7 11/16	5⅛	6¼
K 101	18.0 — 26.5	0.7 db	7 9/16	5⅛	6¼
A 101	26.5 — 40.0	1.0 db	6 13/16	5⅛	6¼

British Columbia, Vancouver, Canada.

"Recent Progress in the Development of High Frequency Transistors," *G. N. Hanson, Bell Telephone Labs., Allentown, Pa.*

"Some Aspects of Semiconductor Noise," *A. Van Der Ziel, Univ. of Minnesota, Minneapolis.*

"Maser Operation at Infrared and Optical Frequencies," *L. C. Levitt, Hughes Research Labs., Culver City, Calif.*

Session 4

Control Systems II—Optimal Design Techniques

Wednesday Morning, May 25

Chairman: *A. H. Koschmann, Univ. of New Mexico, Albuquerque.*

Co-Chairman: *R. M. Hubbard, Boeing Airplane Co., Seattle, Wash.*

"Performance Criteria in Adaptive Control," *C. W. Sarture and J. A. Aseltine, Space Technology Labs., Los Angeles, Calif.*

"Limit Cycle Efficiency of On-Off Reaction Control Systems," *G. W. Freeman, Boeing Airplane Co., Seattle, Wash.*

"Design Aspects of Attitude Control Systems," *M. F. Marx, General Electric Co., Schenectady, N. Y.*

"A Simulator Study of a Two-Parameter Adaptive System," *V. C. Rideout and R. J. McGrath, Univ. of Wisconsin, Madison.*

Session 5

Solid State Electronics II—Solid State Energy Conversion

Session 6

Electromagnetics I—Radio Astronomy

"Radio Emission from the Sun at Decametric Wavelengths," *J. W. Warwick, High Altitude Observatory Univ. of Colorado, Boulder.*

B. S. Yaplee, *Radio Astronomy Br., U. S. Naval Research Lab., Washington, D. C.*

D. D. Cudaback, *Electrical Engineering Dept. Stanford Univ., Stanford, Calif.*

A. E. Lilley, *Harvard College Observatory, Cambridge, Mass.*

Session 7

Control Systems III—Nonlinear and Sampled Data Systems

Wednesday Afternoon

Chairman: *R. E. Hanna, Douglas Aircraft Co., Santa Monica, Calif.*

Co-Chairman: *E. Noges, Univ. of Washington, Seattle.*

"Nonlinear Effects in Servo Control Systems," *R. B. Higley, Autonetics, Downey, Calif.*

"Control of Higher Order Systems Based on Time Optional Regulations," *F. B. Smith, Minneapolis Honeywell, Minneapolis, Minn.*

"An Error Minimization Technique for Sampled-Data Systems," *A. F. Engelbrecht and C. W. Steeg, Jr., Radio Corporation of America, Burlington, Mass.*

Session 8

Electromagnetics II—Very Large Aperture Antennas

"Radar Astronomy: A New Technique for the Study of the Solar System," *R. L. Leadabrand and R. B. Dyce, Stanford Research Inst., Menlo Park, Calif.*

"The Design and Operation of a Two-Mile Aperture Antenna," *W. C. Erickson, Convair Scientific Research Lab., San Diego, Calif.*

"Environmental Antenna Patterns," *J. F. Carpenter, Dalmo Victor Co., Division of Textron, Inc., Belmont, Calif.*

"The Ohio State 360 Foot Radio Telescope," *R. T. Nash, Radio Observatory, Dept. of Electrical Engineering, Ohio State Univ., Columbus.*

Session 9

Student Prize Paper Contest—IRE 7th Region Finals

Wednesday Evening

Chairman: *F. D. Robbins, Univ. of Washington, Seattle.*

Session 10

Engineering Management Symposium—Technical Management of Large Systems

Session 11

Control Systems IV—Biological Control Systems

Thursday Morning, May 26

"The Design of Man-Machine Systems by Means of Quantitative Analysis Techniques of Human Factors Engineering," *O. H. Lindquist, Minneapolis-Honeywell, Minneapolis, Minn.*

"Control Systems Characteristics of the Respiratory System," *A. C. Young, Univ. of Washington, Seattle.*

"Relaxation and Transit Time Oscillations in the Heart," *J. W. Woodbury, Univ. of Washington, Seattle.*

Session 12

Electromagnetics III—Arctic Ionospheric Phenomena

"Distribution of Auroral Radar Disturbances in Alaska During the IGY," *R. S. Leonard, Geophysical Inst., College, Alaska.*

"Sweep-Frequency Backscatter Studies in the Auroral Zone," *H. F. Bates, Geophysical Inst., College, Alaska.*

"High Frequency Studies of the Arctic Ionosphere," *L. Owren and R. D. Hunsucker, Geophysical Inst., College, Alaska.*

"A High Latitude Study of Spread F Echoes," *Z. A. Ansari and L. Owren, Geophysical Inst., College, Alaska.*

Session 13

Solid State Electronics III—Magnetics and Dielectrics

Thursday Afternoon

"Ferroelectric Power Converters," *S. R. Hoh, IT and T Co., Nutley, N. J.*

"New Magnetic Devices for Digital Computers," *D. H. Looney, Bell Telephone Labs., Murray Hill, N. J.*

L. Rimai, Raytheon Co., Waltham, Mass

Session 14

Electromagnetics IV—Terrestrial Electromagnetic Effects

"Terrestrial Propagation of VLF Radio Waves," *J. R. Wait, National Bureau of Standards, Boulder, Colo.*

"Whistlers and Related Phenomena," *R. A. Helliwell, Radioscience Lab., Stanford Univ., Stanford, Calif.*

"Effects of Terrestrial Electromagnetic Disturbances on Wireline Communications," *R. Sanders, Hughes Aircraft Co., Culver City, Calif.*

Fourth National Convention on Military Electronics

SHERATON PARK HOTEL, WASHINGTON, D.C., JUNE 27–29, 1960

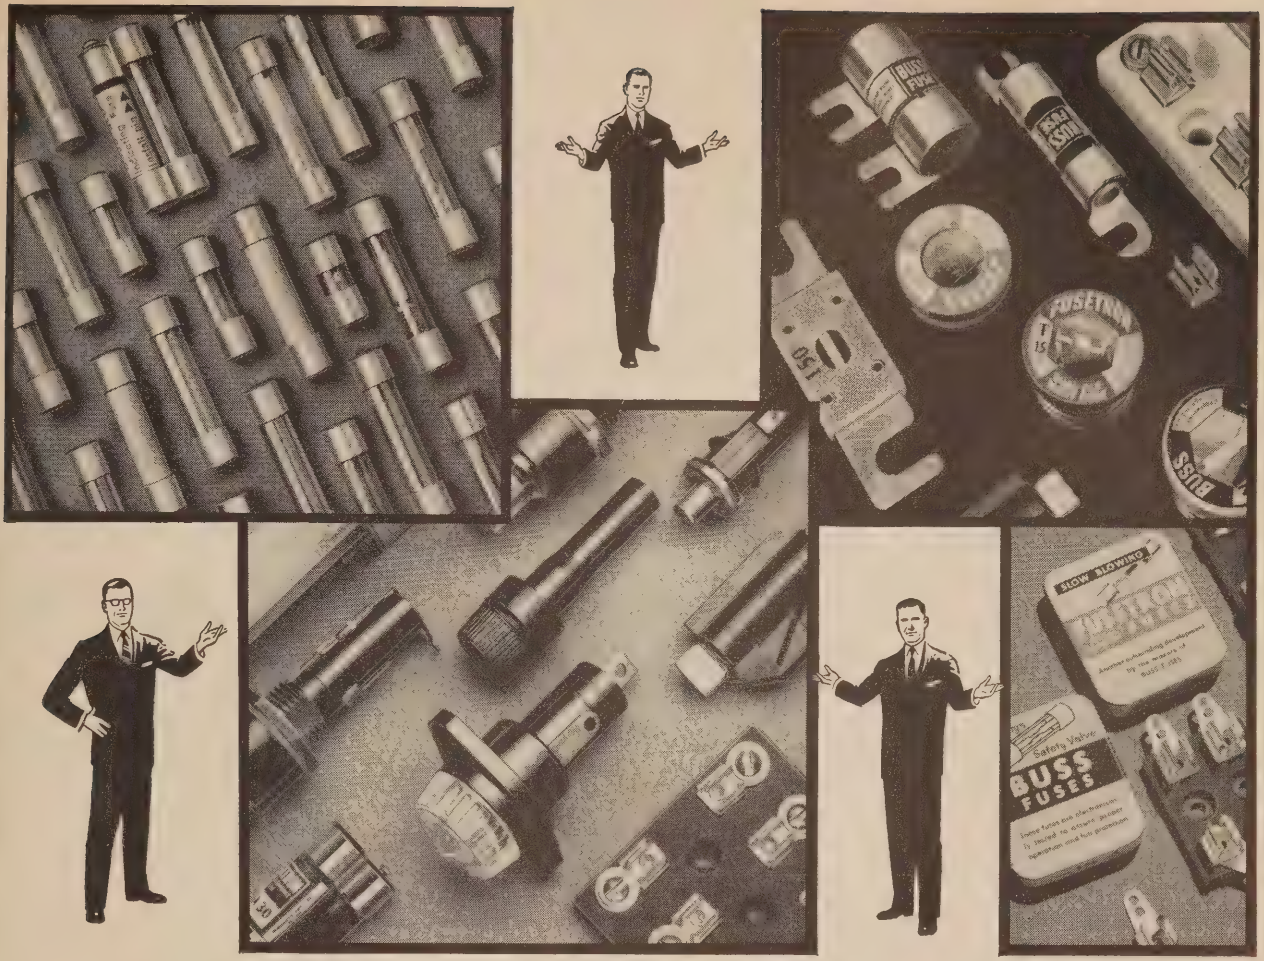
A panel discussion on military research and development will highlight the opening session of the 4th National Convention on Military Electronics (MIL-E-CON 1960) which will be held again this year in Washington, D.C. on June 27–29. This annual meeting is sponsored by the Professional Group on Military Electronics.

Dr. Jerrold R. Zacharias, Professor of Physics at the Massachusetts Institute of Technology, will moderate the discussion by officers from the three military services, including Vice Admiral John T. Hayward, USN, Deputy Chief of Naval Operations (Development) and Major General Leighton I. Davis, USAF, Assistant Deputy Chief of Staff, Development, U.S. Air Force.

The technical program includes 25 sessions, 20 of which will be unclassified. The Air Force Research and Development Command will sponsor five classified sessions at MIL-E-CON 1960; security clearance is required for attendance at these classified meetings. Printed copies of the 1960 *Conference Proceedings*, containing the unclassified papers, will be distributed free of charge to each registrant.

Exhibits of the latest in military components and equipment will fill the exhibit areas of the Sheraton-Park Hotel. The exhibits will run concurrently with the technical sessions.

On the social side, there will be a Keynote Luncheon on Monday, June 27, a buffet and entertainment Monday evening, a Ladies' Breakfast on Tuesday, and the An-



Here are the plain facts!

. . . *why it pays to specify and use dependable* BUSS FUSES

IT'S A FACT! By specifying BUSS fuses, you obtain the finest electrical protection possible — and you help safeguard the reputation of your product for quality and reliability.

IT'S A FACT! BUSS fuses have provided dependable electrical protection under all service conditions for over 45 years—in the home, in industry and on the farm.

IT'S A FACT! To make sure BUSS fuses will give your equipment maximum protection, every one made is tested in a sensitive electronic device. Any fuse not correctly calibrated, properly constructed and right in all physical dimensions is automatically rejected.

IT'S A FACT! Whatever your fuse requirements, there's a dependable BUSS or FUSETRON fuse to satisfy them. Sizes from 1/500 ampere up and there's a companion line of fuse clips, blocks and fuseholders.

IT'S A FACT! The BUSS fuse engineering staff will work with you to help you find or develop the best-suited to your needs. This places the world's largest fuse research laboratory and its personnel at your command to save you engineering time.

For more information on BUSS and FUSETRON Small Dimension fuses and fuseholders, write today for Bulletin SFB.

BUSSMANN MFG. DIVISION, *McGraw-Edison Co.* University at Jefferson, St. Louis 7, Mo. 560

BUSS fuses are made to protect - not to blow, needlessly

BUSS makes a complete line of fuses for home, farm, commercial, electronic, electrical, automotive and industrial use.

FUSETRON
TRUSTWORTHY NAMES IN ELECTRICAL PROTECTION

McGRAW EDISON

nual Banquet Tuesday evening, featuring a prominent guest speaker and the presentation of the Barry M. Carlton Award. The Washington Chapter of PGMIL will be the host at the Keynote Luncheon, with Major General Earle F. Cook, USA, Deputy Chief Signal Officer, as the speaker. Dr. Edward G. Witting, Deputy Director of Research and Development, Office of the Secretary of the Army, and chairman of the Washington Chapter, PGMIL will be the master of ceremonies at this luncheon. A meeting of the Administrative Committee of PGMIL is scheduled for Tuesday morning.

Advance registration fees, which include the *Conference Proceedings*, are $2 for IRE members, $3 for nonmembers, and $1 for students. Deadline for advance registration is June 1. At-the-door registration fees will be $4 for IRE members, $5 for nonmembers, and $1 for students. Tickets for the luncheon are $3.50; for the Ladies' Day Breakfast, $2; for the buffet $5; and for the banquet, $10. Tables seating eight may be reserved for the banquet at $80 each. Mr. Jack Carter, Jansky & Bailey, Inc., 3269 M Street, N. W., Washington 7, D.C., is chairman of the Registration Committee.

Robert H. Cranshaw, Manager, Advanced Space Products, General Electric Company, Utica, New York, is President of MIL-E-CON 1960. Dr. Craig M. Crenshaw, Chief Scientist, Office of the Chief Signal Officer, Department of Defense (Army), is Chairman of the Technical Program Committee.

Monday Afternoon, June 27

Session 1.1—Reconnaissance and Ranging I (Confidential)

Sponsor: Air Research and Development Command.

Moderator: *To be announced.*

"Experimental Evaluation of a Diversity Radar," *P. W. Crist, Airborne Instruments Lab., Melville, N. Y.*

"Radar Density Related to Tactical Troop Concentrations," *R. T. Stefancik, G. C. Arrowsmith, and G. A. Pitsenbarger, Sylvania Electronic Defense Lab., Mountain View, Calif.*

"Instrumentation System for Three-Dimensional Tracking of Underwater Missiles," *C. S. Soliozy and J. M. Formwalt, U. S. Naval Underwater Ordnance Station, Newport, R.I.*

"ITT Secure Ranging and Communication System," *A. E. Nashman, ITT Labs., Nutley, N. J.*

"Identification and Evaluation of Magnetic Field Sources Associated with Magnetic-Anomaly Detector Equipped Aircraft," *P. Leliak, The Martin Co., Baltimore, Md.*

"Inertialess Scanning and Tracking Radar (INSTAR)," *J. R. Karp, The W. L. Maxson Corp., New York, N. Y.*

Session 1.2—Satellite Electronics

Moderator: *To be announced.*

"A Satellite Microwave Telemetry Oscillator Using Traveling-Wave Tube Techniques," *L. A. Roberts, Watkins-Johnson Co., Palo Alto, Calif.*

"Application of Microminiaturization Concepts to Space Guidance Computers," *E. Keonjiam, American Bosch Arma Corp., Hempstead, N. Y.*

"Criteria for the Optimum Design of Active Satellite Communication Systems," *A. R. Giddis, Philco Western Development Lab., Palo Alto, Calif.*

"Satellite Ionosounder," *S. Horowitz, AF Cambridge Research Center, Bedford, Mass., and L. Humphrey, General Electric Co., Ithaca, N. Y.*

"Satellite Reliability Achieved Through Comprehensive Environmental and Functional Testing," *J. A. Chambers, U. S. Army Ordnance Missile Command, Redstone Arsenal, Ala.*

"A Compact UHF Diplexer for Applications Involving Rockets or Satellites," *S. E. Parker, Hughes Aircraft Co., Culver City, Calif.*

Session 1.3—Microwave Devices and Techniques

Moderator: *G. R. Kilgore, Westinghouse Electric Corp., Baltimore, Md.*

"Status of Ultra-Low-Noise Traveling-Wave Tubes and Beam-Type Parametric Amplifiers," *K. Kotzebue, B. P. Israelsen and G. E. St. John, Watkins-Johnson Co., Palo Alto, Calif.*

"New Microwave Devices with Bulk Semiconductors," *H. Jacobs, F. A. Brand, M. Benanti, J. Meindl, and R. Benjamin.*

"Phase Stable Limiting Amplifiers Using Beam Deflection Tubes," *E. R. Wingrove, Jr., General Electric Co., Syracuse, N. Y.*

"Applications of Traveling Wave Tubes to Microwave Circuits," *G. E. Austin, Sylvania Electronic Defense Lab., Mountain View, Calif.*

"Recent Electronic Scanning Developments," *J. P. Shelton and K. S. Kelleher, Aero Geo Astro Corp., Alexandria, Va.*

"Practical Stripline Component Design," *V. T. Norwood, Hughes Aircraft Co., Culver City, Calif.*

Session 1.4—Instrumentation

Moderator: *To be announced.*

"The Pulsed Light Theodolite," *L. A. Jay, U. S. Army Electronic Proving Ground, Fort Huachuca, Ariz.*

"Multiple High-PRF Ranging," *D. H. Mooney and W. A. Skillman, Westinghouse Electric Corp., Baltimore, Md.*

"Recent Achievements in Missile-Borne Magnetic Tape Recorders," *M. M. Siera, Lockheed Aircraft Corp., Palo Alto, Calif.*

"Hit Indicator Techniques for Direct Fire Weapons," *H. Chaskin, U. S. Naval Training Device Center, Port Washington, N. Y.*

"Effects of Atmospheric Pollutants on Electronic Equipment." *H. C. McKee, Southwest Research Inst., San Antonio, Texas.*

"A Delay-Line Synthesized Filter Bank with Electronically Adjustable Impulsive Response," *H. J. Bickel and E. Brookner, Federal Scientific Corp., New York, N. Y.*

Session 1.5—Noise Effects on Precision and Data

Moderator: *To be announced.*

"0.1% Accuracy Variable Speed Control System," *M. Hartman, Fairchild Camera and Instrument Corp., Syosset, L. I., N. Y.*

"Pulse Operation of DC Servo Motors for Lower Thresholds," *D. J. Salonimer and W. E. Yoakum, Guided Missile Agency, Redstone Arsenal, Ala.*

"A Mathematical Analysis of Transients Caused by AGC Reset in Line Switching Amplifier as Used in AN/MSQ-18 (Missile Monitor) Equipment," *1st. Lt. R. A. Perry and SP-4 J. M. Dugan, U. S. Army Air Defense Board, Fort Bliss, Texas.*

"An Analogue Computer for Separating Evoked Physiological Potentials from Background Noise," *W. Korpfl, R. Robinson and J. C. Armington, Walter Reed Army Inst. of Res., Washington, D. C.*

"Precision Frequency Measurement of Noisy Doppler Signals," *W. A. Dean, Ballistic Measurements Lab., Aberdeen Proving Ground, Md.*

"Output Signal-to-Noise Characteristics of Correlators," *B. R. Mayo and D. K. Cheng, General Electric Co., Syracuse, N. Y.*

Tuesday Morning, June 28

Session 2.1—Communications and Data Handling (Confidential)

Sponsor: Air Research and Development Command.

Moderator: *F. Brady, Research and Development Div., Office of The Chief Signal Officer, Dept. of the Army, Washington, D. C.*

"Engineering Analysis of Qualitative Data to Provide a Missile System for Simulation and Vulnerability Studies," *N. Johnson, Sylvania Electronic Defense Lab., Mountain View, Calif.*

"Spasur Automatic Digital Data Assembly System, Part I—The Digital Data Transmission Problem, Part II—Description of the Digital System," *W. B. Poland, Jr., U. S. Naval Research Lab. and M. S. Maxwell, and J. Pinker, U. S. Naval Weapons Lab., Dahlgren, Va.*

"Simulation by Interpretation," *F. W. Sinn, Jr. and J. J. Wolf, Burroughs Corp., New York, N. Y.*

"A Transistorized Digital Range Unit," *R. M. Lucas, Bell Telephone Labs., Inc., Whippany, N. J.*

"Pacific Missile Range Communications," *S. H. Vogt, Dept. of the Navy, Washington, D. C.*

"Evaluation of Video and IF MTI Cancellation Techniques," *E. C. Nordell, General Electric Co., Dewitt, N. Y.*

Session 2.2—Communications I

Moderator: *To be announced.*

"Military Applications for Speech Compression Techniques," *A. J. Strassman, Hughes Aircraft Co., Los Angeles, Calif.*

"Instrumentation Used for Ionosphere Electron Density Measurements," *W. J. Cruickshank, Ballistic Research Lab., Aberdeen Proving Ground, Md.*

"Electron Density Measurements in Hypersonic Projectile Trails," *R. S. Hebbert, U. S. Naval Ordnance Lab., White Oak, Silver Spring, Md.*

"Topology Engineering of Communication Networks," *Dr. K. Ikrath and C. C. Comstock, Hqs. U. S. Army Signal Res. and Dev. Lab., Fort Monmouth, N. J.*

"Frequency Selection," *H. R. Smith, Sierra Vista, Ariz.*

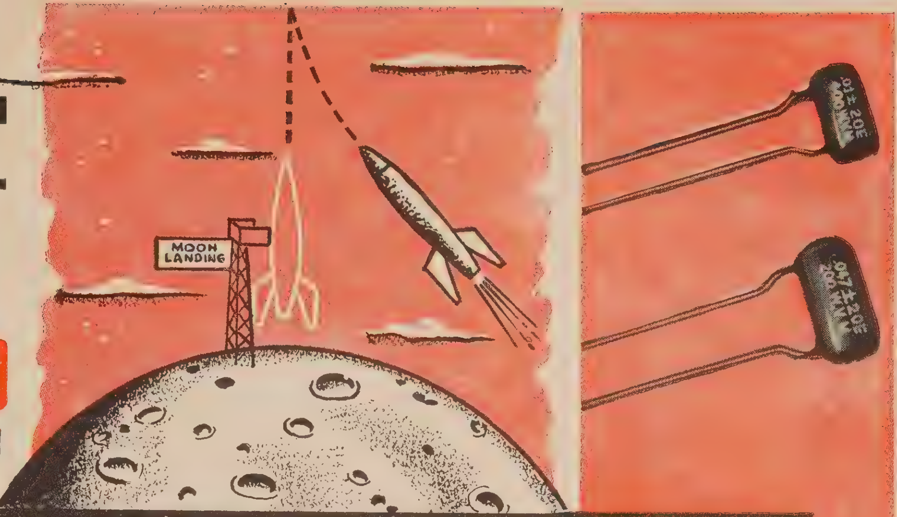
"The Economic Design of Radio Communication Systems by Matching the Message Urgency to the Fading Conditions," *L. P. Yeh, Page Communications Engineers, Inc., Washington, D. C.*

Session 2.3—Reliability

Moderator: *To be announced.*

"Serviceability: Complement to Reliability," *R. H. Wilcox and Cdr. V. R. Wanner, Office of Naval Res., Washington, D. C.*

It could happen... with El-Menco CAPACITORS!



NEW *Mylar-Paper Dipped

CAPACITORS

TYPE MPD

INSURE FAILURE-PROOF PERFORMANCE!

Only 1 Failure in 7,168,000 Unit-Hours for 0.1 MFD Capacitors*

.1±20%E 600WV
.5±20%E 200WV

Setting a new standard of reliability!

*Life tests have proved that El-Menco Mylar-Paper Dipped Capacitors — tested at 100°C with rated voltage applied — have yielded a failure rate of only 1 per 716,800 unit-hours for 1 MFD. Since the number of unit-hours of these capacitors is inversely proportional to the capacitance, 0.1 MFD El-Menco Mylar-Paper Dipped Capacitors will yield ONLY 1 FAILURE IN 7,168,000 UNIT-HOURS.

SUPERIOR FEATURES!

- *Five case sizes in working voltages and ranges:*

200 WVDC —	.018 to .5 MFD
400 WVDC —	.0082 to .33 MFD
600 WVDC —	.0018 to .25 MFD
1000 WVDC —	.001 to .1 MFD
1600 WVDC —	.001 to .05 MFD

SPECIFICATIONS

- **TOLERANCES:** ±10% and ±20%. Closer tolerances available on request.
- **INSULATION:** Durez phenolic resin impregnated.
- **LEADS:** No. 20 B & S (.032") annealed copperweld crimped leads for printed circuit application.
- **DIELECTRIC STRENGTH:** 2 or 2½ times rated voltage, depending upon working voltage.
- **INSULATION RESISTANCE AT 25°C:** For .05MFD or less, 100,000 megohms minimum. Greater than .05 MFD, 5000 megohm-microfarads.
- **INSULATION RESISTANCE AT 100°C:** For .05MFD or less, 1400 megohms minimum. Greater than .05MFD, 70 megohm-microfarads.
- **POWER FACTOR AT 25°C:** 1.0% maximum at 1 KC.

Tuesday Afternoon

Session 3.1—Guidance and Space Technology (Confidential)

Sponsor: Air Research and Development Command.

Moderator: *To be announced.*

"Integrated Design of Antennas for Ballistic Missiles and Space Vehicles," *D. A. Alsberg, Bell Telephone Lab., Inc., Whippany, N. J. and H. W. Redlien, Wheeler Lab., Great Neck, L. I., N. Y.*

"The Space Surveillance System," *Dr. C. E. Cleeton, U. S. Naval Research Lab., Washington, D. C.*

"Orbit Determination for Passive Satellite Detection," *R. B. Patton, Jr., Ballistic Research Lab., Aberdeen Proving Ground, Md.*

"Evaluation of Reliability Prediction Techniques of the Electronics System of the Falcon Missile," *F. A. Barta, Hughes Aircraft Co., Culver City, Calif.*

"Reflections from Meteor Trails Meteorite Experiment," *D. Lynch and C. A. Bartholomew, U. S. Naval Research Lab., Washington, D. C.*

"A Proposed 24-Hour Communications Satellite System," *J. V. Michaels, G. N. Krassner and J. E. Bartow, U. S. Army Signal Res. and Dev. Lab., Fort Monmouth, N. J.*

Session 3.2—Data Handling II

Moderator: *To be announced.*

"Research and Development of New Computer Programming Techniques Required for Mechanization of Machine Learning," *Dr. R. E. Smith, Control Data Corp., Minneapolis, Minn.*

"Pattern Recognition," *J. W. Brouillette and C. W. Johnson, General Electric Co., Syracuse, N. Y.*

"New Techniques in Residual Arithmetic," *M. R. Levine and J. Marx, American Bosch Arma Corp., Hempstead, N. Y.*

"A Note on the Applicability of Error-Correcting Codes," *J. E. Palmer, Radio Corp., of America, Camden, N. J.*

"A Real Time Telemetry Data Transmission System," *H. E. Rennacker, Collins Radio Co., Burbank, Calif.*

"Computer Controlled Automatic Diagnostic and Checkout System for Field Use," *R. J. Brachman, Frankford Arsenal, Philadelphia, Pa.*

Session 3.3—Special Electrical Components

Moderator: *To be announced.*

"Some Aspects of Tunnel Diode Applications," *T. O. Krueger, U. S. Army Signal Res. and Dev. Lab., Fort Monmouth, N. J.*

"The 'Rayistor' an Electrical Transformer Using Optical Coupling," *J. C. Davis, Jr., Raytheon Co., Bedford, Mass.*

"Thin Film Components Based on Tantalum," *R. W. Berry and N. Schwartz, Bell Telephone Lab., Inc., Murray Hill, N. J.*

"Non Steady-State Thermoelectric Generators," *S. R. Hawkins, Lockheed Aircraft Corp., Sunnyvale, Calif.*

"New Developments in the Field of Military Quartz Crystals," *G. K. Guttwein, U. S. Army Signal Res. and Dev. Lab., Fort Monmouth, N. J.*

Session 3.4—Radar

Moderator: *To be announced.*

"Precision Recording of Radar Operation," *C. M. Redman, Hq, White Sands Missile Range, N. M.*

"System Evaluation of Low Noise Radar Sensitivity," *S. Charton and G. Ver Wys, Radio Corp. of America, Moorestown, N. J.*

"The Implementation of the Integrated Mapping System," *J. Boyajean, Fairchild Camera and Instrument Corp., Syosset, L. I. N. Y.*

"A Flush-Mounted VHF Telemetry Antenna with Hemispherical Coverage," *R. C. Payne and P. Painter, Jr., Dynatronics, Inc., Orlando, Fla.*

"The Limitations of Angular Radar Resolution," *Dr. E. Eichler, U. S. Army Ordnance, Frankford Arsenal, Philadelphia, Pa.*

"Internal Ballistic Measuring System," *L. Adelson, Picatinny Arsenal, Dover, N. J.*

Session 3.5—Simulation General

Moderator: *Dr. R. A. Weiss, Scientific Director, Army Research Office, Washington, D. C.*

"Space Simulation with High Gas Release Rates," *W. W. Balwanz and J. M. Singer, Naval Res. Lab., Washington, D. C.*

"Tank vs Tank Synthetic Gunnery Trainer," *I. Friedland, U. S. Naval Training Device Center, Port Washington, N. Y.*

"Radar Simulation," *C. Colbert, Westgate Lab., Inc., Yellow Springs, Ohio.*

"Mathematical Models of Multiple-Gimbal Systems," *Dr. A. Rosenfeld, Budd Lewyt Electronics, Inc., Long Island City, N. Y.*

"Optimization of Test Systems," *J. C. O'Brien, Cooper Development Corp., Monrovia, Calif.*

"Optimum Search Routines for Automatic Fault Location," *S. I. Firstman, The Rand Corp., Santa Monica, Calif., and B. Gluss, Armour Research Foundation of Illinois, Chicago.*

Wednesday Morning, June 29

Session 4.1—Electronic Generation, Switching and Radiation (Confidential)

Sponsor: Air Research and Development Command.

Moderator: *R. I. Cole, Manager, Military Projects Planning, Melpar, Inc., Falls Church, Va.*

"A Very High Gain Experimental Millimeter Foster Scanner," *C. A. Hacking, I-T-E Circuit Breaker Company, Philadelphia, Pa.*

"A Special Purpose Microwave Switch for Anti-jam Operation of Conical Scanning Radars," *S. D. Schreyer and G. Klein, Westinghouse Electric Corp., Baltimore, Md.*

"A Periodically-Focused 10 KW Microwave Traveling-Wave Amplifier," *O. T. Purl and K. W. Slocum, Watkins-Johnson Co., Palo Alto, Calif.*

"Electromagnetic Radiation in Sea Water," *E. J. Hilliard, U. S. Naval Underwater Ordnance Station, Newport, R. I.*

"Self-Focusing Technique for Large Arrays," *P. W. Howells, General Electric Co., Dewitt, N. Y.*

"A Radar Technique Using an Electro-Optical Two-Dimensional Filter, Part I—Principles of Operation, Part II—An Experimental Model Employing a Delay-Line Light Modulator," *L. Lambert, Moses Arm, and Isaac Weissman, Columbia Univ., New York, N. Y.*

Session 4.2—Communications II

Moderator: *To be announced.*

"Operational Testing of a Long Range Rocket Communication System," *B. J. Huffman, Hughes Aircraft Corp., Culver City, Calif., and W. F. O'Neil, C & N Lab. WADD, Wright-Patterson AFB, Ohio.*

"A Long Range Rocket Communication System," *W. L. Exner and E. R. Gaul, Hughes Aircraft Co., Los Angeles, Calif.*

Electron Tube News ...from SYLVANIA

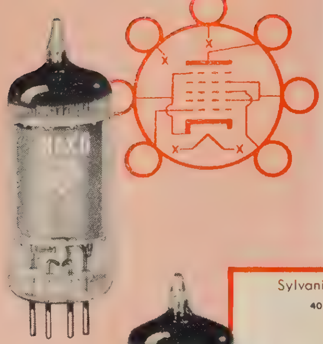
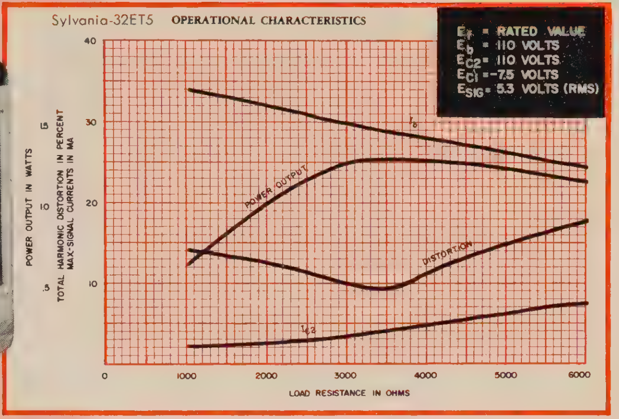
90 120 130 160

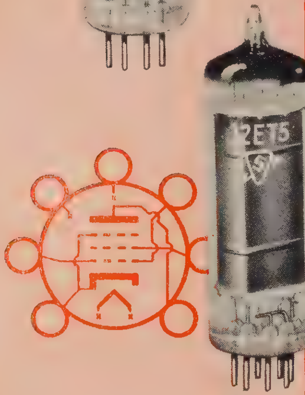
Cool operation sparks home-radio sales when you design around

SYLVANIA 100-mA ALL-AMERICAN FIVE

Originated by Sylvania—the 100-mA All-American Five requires ⅓ less heater power, opens new design possibilities and offers significant merchandising opportunities. Now, tube layout is comparatively unrestricted, cabinet styling is more flexible. Cost reductions in cabinetry, circuitry and components are within easy grasp. Tube reliability is enhanced. Printed circuit techniques can be used advantageously. Here, then, are important advances in home radio design—made possible by the Sylvania 100-mA All-American Five.

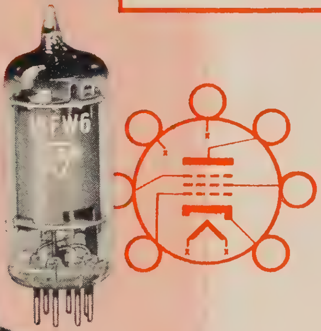




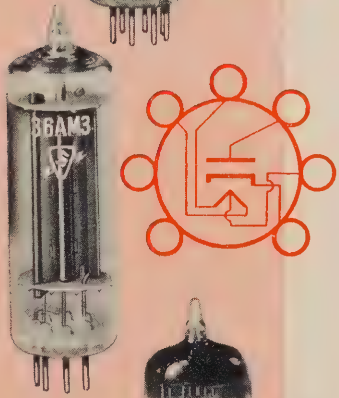


Named to the All-American Five are: 18FW6, semi remote cut-off pentode; 18FX6, pentagrid converter 18FY6 high mu triode-double diode; 32ET5, bean power pentode; and the 36AM3, half-wave rectifier—a tube complement with proven field experience.

Lower ambient temperature increase design flexibility and offer substantial economies. Radio cabinets utilizing this carefully mated complement show temperature reductions of 20-25%. The area of the power output tube shows an even greater temperature decrease—as much as 30%. As a result, less expensive plastics can be used. Vertical chassis can be designed without special heat shielding. Placement of the power output tube is no longer critical because of heat—wide, outside "berths" are unnecessary—designs can be compact. Printed circuit boards may be used without deterioration in set life and performance caused by high ambient temperatures.

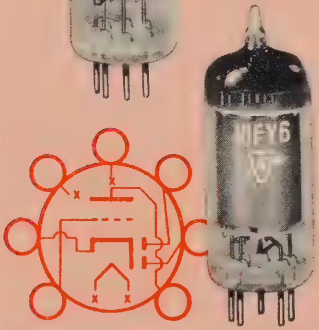


Tube reliability is increased. Sylvania heater design of the 100-mA line provides for more balanced distribution of the heater voltages in the heater string. Surge voltages across individual tubes are minimized.



Sylvania 100-mA All-American Five can be used in existing 150-mA designs with a minimum of redesign time. The 100-mA tube complement presents many advantages that can be directly translated into consumer benefits and increased home radio sales.

New developments in the 100-mA line. Sylvania is developing further tube complements that will incorporate the inherent advantages of a cooler-operating 100-mA line. These include a four tube line for home radio sets, a complement for FM radio receivers, and two new types that hold exciting possibilities for quantity-produced Hi-Fi.



Your local Sylvania Sales Engineer will gladly give you the whole story on the Sylvania 100-mA line. Call him or write Electronic Tubes Division, Sylvania Electric Products Inc., Dept. 195, 1740 Broadway, New York 19, New York.

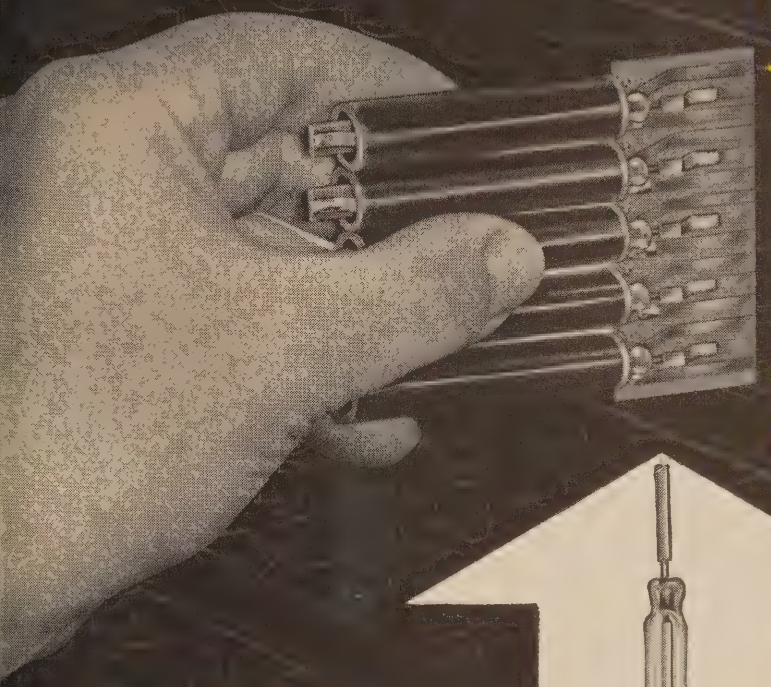
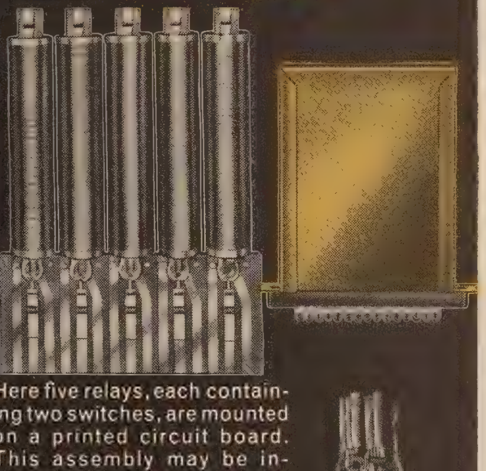
CLAREED®

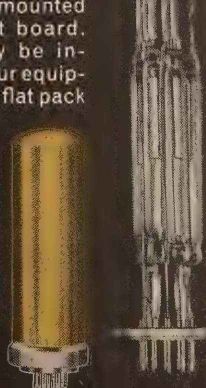
FITS INTO *YOUR* DESIGN!



PACKAGED TO MEET YOUR REQUIREMENTS



Here five relays, each containing two switches, are mounted on a printed circuit board. This assembly may be inserted directly into your equipment or enclosed in a flat pack container.



These six switches are clustered to form the core of a single electromagnetic coil, and encased in a cylindrical steel container.

ACTUAL SIZE

Basic element of CLAREED relays is this switch capsule. A pair of magnetically operated contacts is hermetically sealed in an atmosphere of inert gas. The capsule combines extreme simplicity with high reliability and long life. It has excellent low-level characteristics.

CLAREED Sealed Contact Reed relays put you . . . the designer . . . in the driver's seat. They are simple in design, flexible in assembly. They are packaged and mounted to comply with *your* mechanical design configuration . . . even on your own circuit board. CLAREED relays are ideal components for transistor-drive applications, computers, data-processing and other high speed equipment.

Contacts are hermetically sealed in inert gas. Tens of millions of operations are assured since contact contamination is completely precluded. Hundreds of millions of operations are possible when operated up to ½ rated load.

If you use relays, it will pay you to know all about CLAREED . . . an entirely new concept in relay design. Address C. P. Clare & Co., 3101 Pratt Blvd., Chicago 45, Illinois. In Canada: C. P. Clare Canada Limited, Box 134, Downsview, Ontario. Cable Address: CLARELAY. *Send for Bulletin CPC-5.*

FROM DELCO RADIO NEW IDEAS FOR DEFENSE

HIGH CAPACITY STATIC INVERTERS WITH NO MOVING PARTS

Delco Radio's high capacity Static Inverters and Converters fill a critical need in missile guidance and control—offering extremely reliable, very highly regulated power of precise frequency. The Static Inverters use direct crystal-frequency control and digital logic circuits to produce accurate, single or polyphase power output. They have no moving parts. There is nothing that can get out of adjustment. Electrical characteristics are: High Capacity—150 to 4,000 volt-amperes. High Efficiency—65 to 90% depending on power and control (precision and regulation) required. Accurate Phase Angle Control—to 0.5 degree. Precise Frequency Control—up to 6 parts per million maximum variation under all load and environmental conditions. Voltage Amplitude Control—to ±1% no load to full load. Low Distortion—typically 2% total harmonic distortion. Delco Radio has developed and produced power supplies for missiles such as the Air Force's Ballistic Intermediate Range Thor, Intercontinental Titan, and the pilotless aircraft Mace. For further information on military electronics, write to our Sales Department. *Physicists and electronics engineers: Join Delco Radio's search for new and better products through Solid State Physics.*

Change

Daven solves your solid-state power supply problems!

Take advantage of Daven's experience in designing extremely compact, light-weight, high temperature units, which can withstand the most severe altitude, shock, and vibration environments. Let us engineer solid-state supplies for your missile-borne, airborne, shipborne, underwater or ground support equipment.

Converters

- DC input voltage from 6 volts to 230 volts
- DC output voltage from 1 volt to 15 kilovolts
- DC output current from microamperes to 100 amps
- Dynamic regulation, ripple, stability as required

Inverters

- DC input voltage from 6 volts to 230 volts
- AC output from 20 VA to 2500 VA
- 60–400–800–1600–2000 cycles per second
- One, two or three phase, any voltage level
- Voltage and frequency regulation 0.1% to 10% as required
- Output waveform — sine or square wave

Frequency Changers

- 20 VA to 2500 VA
- Change to or from any of these frequencies: 60–400–800–1600–2000 cycles per second
- Voltage and frequency regulation 0.1% to 10% as required

Write for complete information, including your application and requirement data.

TODAY, MORE THAN EVER, THE DAVEN Ⓓ STANDS FOR DEPENDABILITY

NEWS New Products

New Cathode Ray Tubes

Three years of research & development in the laboratories of **Thomas Electronics Inc.**, Passaic, N. J., have resulted in a new technique in the manufacture of industrial-military cathode ray tubes used in instrument and radar applications. The development, involving new processes, techniques and materials, permits the aluminizing of cathode ray tubes operating with anode potentials of as low as 2 kilovolts. Previously tubes were aluminized only at high voltages greater than 5 to 6 kilovolts.

Aluminized cathode ray tubes offer many advantages, one of which is a substantial increase in the screen brightness. Brightness can now be augmented by as much as 90% in low voltage cathode ray tubes, resulting in an increase in the writing rate, which is especially desirable in photographic and visual applications. Alternatively, the increase in brightnesss permits a reduction in the beam current for the average display which results in a consequent reduction in line width and better overall resolution.

When the faceplate of an ordinary cathode ray tube is touched with the hand, the effect may be an impairment of the resolution of the display, or the display may shift its position. These adverse effects are eliminated with an aluminized screen, since its overall screen potential is made uniform by the conductivity of the aluminum layer.

Another advantage is the elimination of cathode glow and the back reflection of light from the walls of an aluminized cathode ray tube resulting in a marked improvement in contrast for photographic and visual applications. Other improvements include the reduction or elimination of ion burns for magnetic deflection types and significantly longer overall tube life and reliability.

The aluminizing development can be incorporated into the manufacture of all existing JEDEC cathode ray tubes operating in the range between 2 to 8 kilovolts. Prototypes of the 5ADP- and 5AQP-types will be made available shortly.

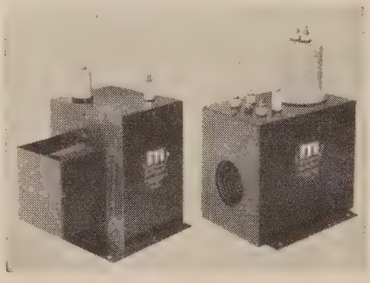
The first user of one of the low-voltage aluminized tubes is Analab Instrument Corp. which has worked jointly with Thomas in setting the specifications and has been evaluating performance of prototypes for oscilloscope applications.

In addition to oscilloscope applications, the tubes are suited for radar displays and any other display systems requiring the ultimate in light output and screen stability.

These manufacturers have invited PROCEEDINGS readers to write for literature and further technical information. Please mention your IRE affiliation.

Pulse Transformers And Reactors

Custom engineered pulse transformers and their associated charging reactors are now available from **Manson Laboratories,** P. O. Box 1214, Stamford, Conn. Pulsed viewing transformers, mono-and bifilar types, and transformers for magnetron and klystron applications can be produced in quantity for circuits rated up to 250 kv. Illustrated in photo are two examples of this custom engineering: On the left a bifilar pulse transformer with recessed bellows providing a wide temperature tolerance, 30 kv rated output, step up ratio 1:5, the Bifilar Secondary supplies a magnetron with 3 amperes heater current. On the right; a charging reactor (4.5 henry), high "Q," linear over a wide dc current range, insulated for operation at 10 kv dc supply voltage. All components will meet applicable MIL specs when required.



Inquiries regarding special applications and specifications are invited. Brochure #XFR260 and data application forms are available upon request.

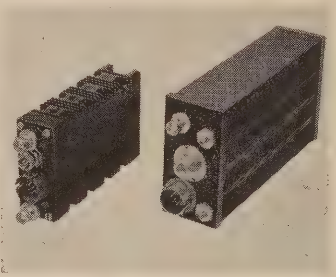
CGS Laboratories Now Trak Electronics

Elton T. Barrett, president, **CGS Laboratories, Inc.,** Wilton, Conn., announces that henceforth the company will carry on operations under the name of **Trak Electronics Co.** The corporate name remains unchanged for the present, and the business will be conducted under the name Trak Electronics Co., Division of CGS Laboratories, Inc.

In announcing the change, Mr. Barrett said: "The principal reasons for the change are the adoption of a name by another company similar to our corporate name, a desire to avoid the limitations implied by the word 'Laboratories,' and to facilitate promotion to the trade mark 'TRAK,' which already has acceptance in the trade."

Radar Beacon

Telerad Manufacturing Corp., 1440 Broadway, New York 18, N. Y., announces a new, compact radar beacon MODEL SRT-3081. The outstanding features of this beacon are:



Environmental conditions—Temperature: −54°C to +125°C. Vibration: 10 to 100 cps at 25 G. Acceleration: 50 G. Altitude: 60,000 ft. Shock: 15 G.

Receiver—Frequency range: 2750–2950 mc. Bandwidth: 6–12 mc at 3 db points 35 mc maximum at 40 db down.

Triggering sensitivity: −41 db (min.). Interrogation: Single or double pulse. Frequency stability: ±2 mc. Size $1\frac{1}{4}'' \times 2\frac{7}{8}'' \times 5\frac{3}{4}''$.

Transmitter—Frequency range: 2750–2950 mc. Frequency stability: ±2 mc. Pulse power: 100 watts peak (min.) Pulse repetition rate: 2000 pp. Pulse width: 0.65±0.05 microsecond. Delay: 1.5 microseconds. Range jitter: 0.1 microsecond. Size: $2'' \times 3\frac{5}{8}'' \times 7\frac{9}{16}''$. Weight: 3.45 lbs. Power supplies available on special order.

For more detailed information on this beacon and other Telerad products that embrace the L, S, C, X and K bands, write to the firm.

Connector Catalog

Automatic Metal Products Corp., 323 Berry St., Brooklyn 11, N. Y., has published a radio frequency connector guide and technical manual.

Over two years of extensive research, development and preparation has gone into the production of this coaxial connector volume.

In addition to the connector illustrations, diagrams, and numerical designations, this volume will contain technical information on the use of connectors, a comprehensive section devoted to coaxial cables, and complete cable assembly instructions for all connectors listed. An additional section devoted to Automatic's coaxial relays and switches is also included.

Further information may be obtained by writing to the firm.

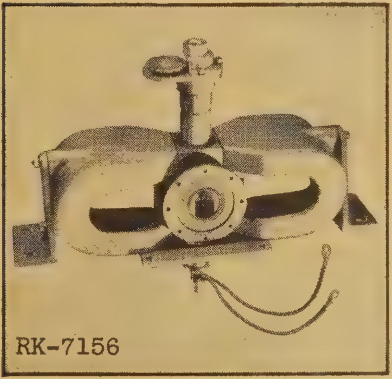
NEW RAYTHEON MAGNETRONS FOR A WIDE RANGE OF APPLICATIONS

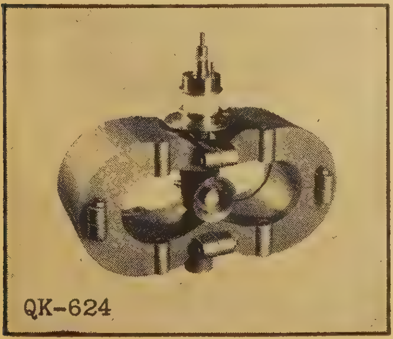
Designed for C-band systems requiring tunability, the RK-7156 magnetron has a minimum peak power output rating of 250 kilowatts over a frequency range of 5,450 to 5,825 megacycles. Applications include a flight-tested, revolutionary airborne weather radar system. The RK-7156 is in quantity production.



RK-7156

* * *

X-band magnetron for airborne search radar provides one megawatt minimum peak power and 875 watts average power within a frequency range of 9,340 to 9,440 Mc. Designated QK-624, this pulsed-type tube is liquid cooled and should give at least 1,000 hours of reliable service.



QK-624

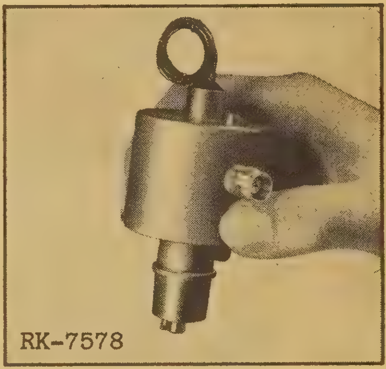
* * *

For ground-based and airborne radar systems, the RK-7529 magnetron provides a 2.0 microsecond pulse of 3.5 megawatts minimum peak power over 2,700 to 2,850 Mc. This liquid-cooled tube is interchangeable with other fixed-frequency S-band tubes operating at similar power levels.

RK-7529

* * *

A one kilowatt beacon magnetron, the RK-7578 weighs only 14 ozs., yet will withstand vibrations of 15 G's at 20 to 2,000 cycles and shock up to 100 G's. It is mechanically tunable and covers the 5,400 to 5,900 Mc range.



RK-7578

* * *

Developed to withstand extreme environmental conditions, the RK-7449 magnetron is a lightweight, compact tube with a minimum peak power output of 45 kilowatts at the operating frequency of 24 kmc. The RK-7449 is required to withstand repeated shocks of 50G. Stable operation is guaranteed at vibration frequencies up to 2,000 c.p.s. with 30G applied.

RK-7449

For the highest standard of Accuracy and Reliability

MARCONI INSTRUMENTS

for Precise Measurement

LOW CAPACITANCE BRIDGE
Model 1342

- Capacitance range: 0.002 $\mu\mu$F to 1,111 $\mu\mu$F, ± 0.2% accuracy.
- Shunt-resistance range: 1 to 1,000 MΩ.
- Suitable for in-situ measurements.
- Decade switching and readout.
- Independent indication of resistive component.

Capacitances down to 0.002 $\mu\mu$F can be measured with speed and precision by means of this three-terminal transformer ratio-arm bridge. Its exceptional discrimination and stability make it suitable for such applications as the measurement of the temperature coefficient of capacitors or changes in tube interelectrode capacitance. The bridge measures the capacitance between any two terminals of a 3-terminal network and is virtually unaffected by the impedance between either of these terminals and the third point. Connection to the component under test can be made via long leads without affecting measurement accuracy. Remote or wired-in components can be measured in-situ without the need to disconnect associated circuits.

20-MC SWEEP GENERATOR
Model 1099

Can be used in conjunction with any oscilloscope for direct display of video response characteristics up to 20 MC. Frequency is indicated by crystal-controlled marker pips, and a special circuit provides for differential amplitude measurements, enabling relative response to be determined with a discrimination better than 0.01dB. **Frequency Swept Output:** Frequency Range: Lower limit 100 kc, Upper limit 20 MC. Output level: Continuously variable from 0.3 to 3 volts. Output Impedance: 75Ω. **Time Base:** Repetition Rate: 50 to 60 cps. Output for c.r.o. X deflection: 250 volts. **Frequency Markers:** At 1 MC intervals; every fifth pip distinctive and crystal controlled.

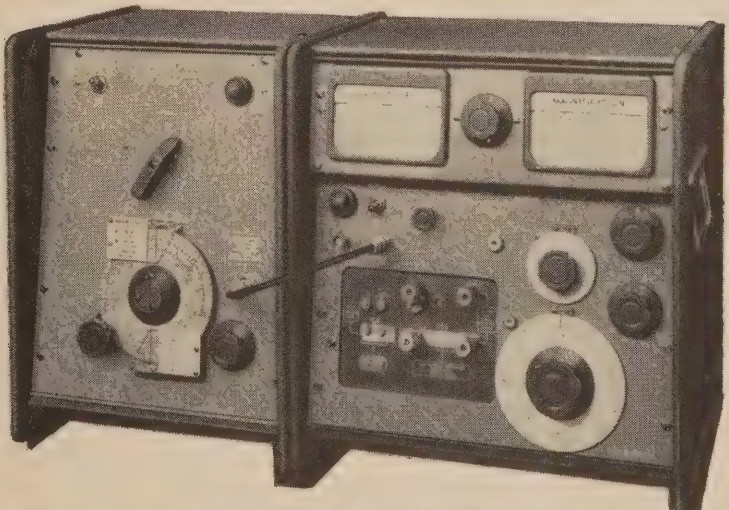
Model 1064A/2 for MOBILE RADIO

This FM Signal Generator provides RF outputs of 30 to 50, 118 to 185, and 450 to 470 MC, with FM at one fixed deviation and 0-15 kc variable: IF crystal outputs at five spot frequencies, (xtals not supplied) and also an AF output. High frequency stability, quick warm up and accurate FM have been obtained by use of modern semi-conductor components. FM is produced by a varactor and the power supply is transistor stabilized with zener diode reference.



Q METER
Model 1245

Here for the first time is a single Q Meter covering the range AF to VHF.

Frequency Range: 1 kc to 300 MC. Measures Q: 5 to 1,000: accuracy 5% at 100 MC. **Q Multiplier:** x0.9 to x2. **Delta Q:** 25-0-25. Test Circuits: separate LF and HF test circuits have ranges of 1 kc to 50 MC and 20 to 300 MC. **Capacitance Range:** 7.5 to 110 μμF with 1-0-1 μμF incremental, for either test circuit; 20 to 500 μμF for LF test circuit. **Shunt Loss:** 12 MΩ at 1 MC, 0.3 MΩ at 100 MC. **External Oscillators:** Model 1247, 20 to 300 MC. Model 1246, 40 kc to 50 MC. Model 1101, 20 cps to 200 kc.

IRE People

Wayne D. Brodd (A'54), has been promoted to the position of advisory engineer in the IBM 7070 Engineering Department of the IBM Product Development Laboratory at Poughkeepsie, N. Y., where he is engaged in the New Product Engineering effort on the 7070 Unit Record Equipment, and system coordination with Endicott and Rochester Engineering groups.

He joined IBM in 1950 as a customer engineer trainee at Evanston, Ill. He was transferred to Poughkeepsie in 1953 as a technical engineer on the 702 input/output development and advanced to associate engineer in 1955 where he became engaged in work on the 774 Tape Data Selector. He attained the status of staff engineer in 1958, his position until his recent advancement.

Mr. Brodd is a graduate of the University of Illinois, Urbana, in 1950 with the B.S.E.E. degree.

❖

Donald W. Burns (A'56), has been advanced to the position of technical assistant to Arthur J. Hatch, vice president and general manager of Stromberg-Carlson's Commercial Products Division, according to an announcement issued by Mr. Hatch. Stromberg-Carlson is a division of General Dynamics Corporation.

D. A. Burns

In this new position Mr. Burns will be responsible for development and coordination of a variety of technical programs. Prior to this appointment he was chief engineer in the Commercial Products Division.

He has been with Stromberg-Carlson since 1954, when he joined the firm as a staff engineer to the manager of quality control in the Radio and Television Division. Subsequently he served as an engineer in the Research Division, as a senior design engineer in the Special Products Division, and as chief engineer of the Commercial Products Group in the Special Products Division. Earlier he had been a design development engineer with Sylvania Electric Products Corporation in Buffalo.

Mr. Burns attended the University of Buffalo and received the B.A. degree in mathematics from the University of Rochester. He is a member of the Rochester Society for Quality Control, and is chairman of the Committtee on Sound Apparatus of the Electronic Industries Association.

❖

Roy J. Sandstrom, Bendix Systems Division, General Manager, has announced the appointment of **James A. Burns** (A'54) as Director of Long Range Planning for the Bendix Systems Division. He will fill the position vacated by L. B. Young who recently became Assistant General Manager of the Division. Mr. Burns was formerly Head of Technical Planning under Mr. Young.

As the new Director of Long Range Planning, he will direct the Technical Planning and Marketing activities of the division and will coordinate customer requirements into the preliminary design studies as well as preparation and presentation of proposals. He will also integrate the capabilities of other Bendix Divisions and potential subcontractors into major systems investigation.

He received the B.S. degree in electrical engineering from the University of Michigan, Ann Arbor, in 1952, majoring in electronics. After graduation, he joined the Willow Run Laboratories of the University of Michigan Engineering Research Institute where he participated in the fields of analog computation, weapons systems design and analysis, air defense system design, communication equipment design and test, and battle area surveillance system and equipment design and analysis. During this period, he was Project Engineer on systems design for low-altitude defense and other weapons systems work.

In the field of battle area surveillance, he served from 1953 to 1957 in various capacities on Project Michigan, a triservice program to improve the intelligence gathering capabilities of the service. He was engaged primarily in radar system design and analysis, particularly in the field of MTI and the processing and display of radar data. He performed a survey of all existing or development radar equipment to establish its application to battle area surveillance. In addition, he performed detailed evaluation and test of several specific radar systems, particularly those employing MTI.

In addition to his work in radar, he also participated in the establishment of requirements for battle area surveillance systems, including evaluation and test, using television, microwaves, infrared, acoustics, and optical devices as well as navigational subsystems of both the ground-based and self-contained types. In this connection, he performed system design involving sensory devices, data processing and display techniques, and communications. He also participated in the test of battle area surveillance and intelligence processing equipment in large-scale Army maneuvers. He was a consultant to the Bendix Systems Division on air defense and air traffic control problems in 1956, and joined Bendix in January, 1957.

SPACE AGE TV— WITH EIMAC CERAMIC TUBES

Lockheed's new miniature TV transmitter and camera have special significance for a space-curious world. They may one day help unravel some of the mysteries of the unknown as they soar through the outer reaches of space in a sophisticated sattelite.

At the heart of the tiny transmitter is an Eimac ceramic tetrode, the 4CX300A. Eimac ceramic tubes can take tough assignments like this in their stride, with performance "extras" that mean outstanding reliability.

Eimac advanced ceramic design makes possible a compact tube capable of maintaniing exceptional stability. Even under conditions of severe shock, vibration and accelerations up to 20g at frequencies from 20 to 2000 cycles per second no tube damage will result. Rugged, reliable power in a small package.

EITEL-McCULLOUGH, INC. • San Carlos, California

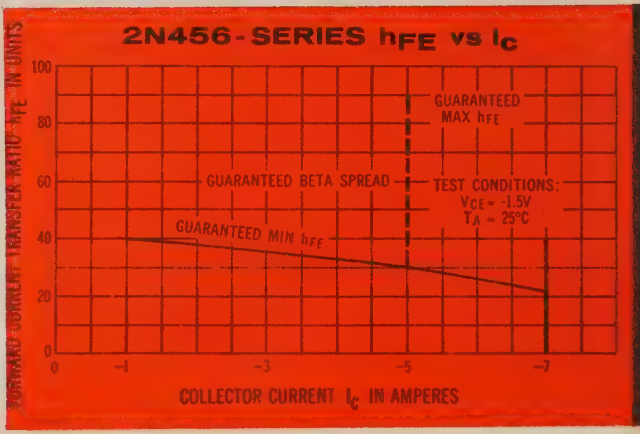
Eimac

Today, over 40 ceramic tube types pioneered by Eimac engineering and research are available for use under adverse conditions. Whenever you have an application that requires compact tubes that *can take it*, investigate the many advantages of Eimac advanced ceramic-metal construction.

FULL LINE OF HIGHEST BETA GE

New TI high-efficiency emitter gives you high beta germanium power transistors!

Now minimum and maximum betas are guaranteed from 20 to 60 at the maximum current rating f I_C = 25 amps in new TI 2N514 series tran-istors. New high efficiency emitter makes pos-ible greatly improved specifications for TI N456, 2N511, 2N512, 2N513, 2N514, and N1021 series alloy-junction germanium power ransistors.



I gives you design leadership in quality germanium power transistors

INCREASED BETA THROUGH HIGH-EFFICIENCY EMITTER

Emitter efficiency can be improved by increasing he ratio of resistivities between the emitter and ase region. For example, when a 10 ohm-entimeter resistivity germanium wafer is used s the base material, it is advantageous to have ess than a .01 ohm-centimeter resistivity emitter egrowth region. Since initial doping of the ermanium crystal establishes base resistivity, he ratio can be changed only by varying the mitter material. TI utilizes an emitter material hat results in a lower emitter resistivity and an ncreased emitter efficiency, plus providing the igher beta at high currents.

J. G. Anderson

Jack G. Anderson (A'56) has been appointed vice president for government relations at Stromberg-Carlson, Vice President and General Manager Allan R. Shilts has announced. Stromberg-Carlson is a division of General Dynamics Corporation.

Mr. Anderson comes to Stromberg-Carlson from Hoffman Electronics Corporation of Los Angeles, where he was vice president for marketing. He had been with Hoffman since 1954, first as manager of Air Force operations and later as director of military marketing.

From 1942 to 1954 he served with the U. S. Air Force in many assignments throughout the United States, Europe, Africa and the Pacific. He was a major when discharged.

Mr. Anderson attended the University of Louisville and received the B.S. degree from the USAF Institute of Technology in Dayton, Ohio.

He is a past president of the Dayton Wright Chapter of the Armed Forces Communications and Electronics Association and is a member of many other organizations, including the American Rocket Society, Institute of Aeronautical Sciences, Air Force Association, Air Traffic Control Association, American Ordnance Association, Association of the U. S. Army, and the Navy League.

❖

Ralph J. Bahnsen (S'54-A'55–M'59), has been promoted to the position of advisory engineer in the Systems Engineering Department of Advanced Computational Systems at the IBM Product Development Laboratory in Poughkeepsie, N. Y. He is in charge of analysis work on an advanced Data Processing System.

He joined the company in June, 1954 as a technical engineer working on the 702 Computer. He was transferred to Kingston in 1955 and returned to Poughkeepsie in 1956, attaining the status of associate engineer. He was engaged in the 738 memory and logical design of an advanced data processing system. He became a staff engineer in 1958, his position until his recent promotion.

Mr. Bahnsen attended Queens College and received the B.E.E. degree from the College of the City of New York in 1954.

❖

Dr. Nicholas A. Begovich (S'41–A'48–M'58), has been appointed assistant man-

NEW!
CLEVITE
CLEVITE

ADVANCED DESIGN POWER TRANSISTORS FROM CLEVITE

Three new lines of germanium power transistors by Clevite feature new advances in controlled gain spread, fully specified collector-to-emitter voltage characteristics and low current leakage — even at maximum voltages and high temperatures.

The new 8 ampere switching series can be used to replace the older, more costly ring-emitter types in 3 to 8 ampere service.

The new 25 ampere switching type offers exceptionally low saturation voltage and is available with either pin terminals or solder lugs.

The new Spacesaver design not only affords important savings in space and weight, but its significantly improved frequency response means higher audio fidelity, faster switching and better performance in regulated power supply applications. Its low base resistance gives lower input impedance for equal power gain and lower saturation resistance, resulting in lower "switched-on" voltage drop. Lower cut off current results in better temperature stability in direct coupled circuits and a higher "switched-off" impedance.

CLEVITE NOW OFFERS THESE COMPLETE LINES

Switching Types	Amplifier Types
5 ampere	2 watt
8 ampere	4 watt
15 ampere	2 watt Spacesaver
25 ampere	
3 ampere Spacesaver	

All Clevite germanium power transistors are designed for low thermal resistance, low base input voltage, low saturation voltage and superior current gain.

For latest data and prices or application assistance, write for Bulletin 60 . . .

ENGINEERING TEAMWORK IN SPACE EXPLORATION

Engineers and scientists interested in a wide range of activities will appreciate the advanced nature of research and development projects under way at JPL. These projects include research, basic and applied, in Electronics, Solid State Physics, Propulsion, Aerodynamics, Structures and Materials and the design, development and analysis of space probes and satellites. Individually responsible engineers and scientists work together as a thoroughly integrated team in accomplishing the complete objective.

Programs involve guidance, telemetering, data recording and reduction, instrumentation, structures, propulsion, materials, solid state physics, components, heat transfer problems and systems analysis and are constantly influenced by continuing JPL space exploration research providing individuals with challenging assignments in almost every phase of engineering and science. Staff progress in diverse fields of activity is constantly being made.

Pioneering in basic research, applied research and development engineering in space exploration proves to be a stimulating attraction for engineers and scientists with innate curiosity and intense interest in the future of space exploration.

More men of this type are needed — if you believe you are qualified for the JPL team, send in your resume today.

ESC DEVELOPS DELAY LINE WITH 170 to 1 DELAY TIME/ RISE TIME RATIO

Model 61-34 Perfected
For Specialized
Communications Application

PALISADES PARK, N. J.—An entirely new Lumped-Constant Delay Line, with a proven 170 to 1 delay time/rise time ratio, has been announced by the ESC Corporation, Palisades Park, N. J. The new delay line, known as Model 61-34, was specifically designed for a specialized communications application calling for the exceptionally high delay time/rise time ratio.

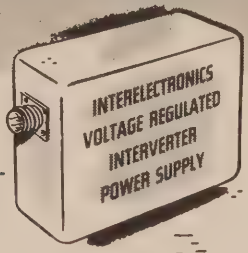
ESC, the world's leading manufacturer of custom built and stock delay lines, is already widely recognized in the electronics industry for its exceptional engineering advances. In October, 1958, ESC broke through an existing design barrier and produced a delay line with a 145 to 1 delay time/rise time ratio. It had been thought, prior to the announcement of the Model 61-34, that ESC had reached the ultimate in this type of delay line.

SPECIFICATIONS OF NEW DELAY LINE
MODEL 61-34

Delay time/rise time ratio: 170/1
Delay: 200 usec.
Rise time: 1.16 usec.
Attenuation: less than 2 db
Frequency response: 3 db = 325 KC
50 taps with an accuracy of ±0.2 usec. at each tap.

Complete technical data on the new unit can be obtained by writing to **ESC Corporation, 534 Bergen Boulevard, Palisades Park, New Jersey.**

PROVEN RELIABILITY—
SOLID-STATE POWER INVERTERS
over 260,000 logged hours— voltage-regulated, frequency-controlled, for missile, telemeter, ground-support, 135°C all-silicon units available now—



Interelectronics all-silicon thyratron-like gating elements and cubic-grain toroidal magnetic components convert DC to any desired number of AC or DC outputs from 1 to 10,000 watts.

Ultra-reliable in operation (over 260,000 logged hours), no moving parts, unharmed by shorting output or reversing input polarity. Wide input range (18 to 32 volts DC), high conversion efficiency (to 92%, including voltage regulation by Interelectronics patented reflex high-efficiency magnetic amplifier circuitry).

Light weight (to 6 watts/oz.), compact (to 8 watts/cu. in.), low ripple (to 0.01 mv. p-p), excellent voltage regulation (to 0.1%), precise frequency control (to 0.2% with Interelectronics extreme environment magnetostrictive standards or to 0.0001% with fork or piezoelectric standards).

Complies with MIL specs. for shock (100G 11 mlsc.), acceleration (100G 15 min.), vibration (100G 5 to 5,000 cps.), temperature (to 150 degrees C), RF noise (I-26600).

AC single and polyphase units supply sine waveform output (to 2% harmonics), will deliver up to ten times rated line current into a short circuit or actuate MIL type magnetic circuit breakers or fuses, will start gyros and motors with starting current surges up to ten times normal operating line current.

Now in use in major missiles, powering telemeter transmitters, radar beacons, electronic equipment. Single and polyphase units now power airborne and marine missile gyros, synchros, servos, magnetic amplifiers.

Interelectronics—first and most experienced in the solid-state power supply field produces its own all-silicon solid-state gating elements, all high flux density magnetic components, high temperature ultra-reliable film capacitors and components, has complete facilities and know how —has designed and delivered more working KVA than any other firm!

For complete engineering data, write Interelectronics today, or call LUdlow 4-6200 in New York.

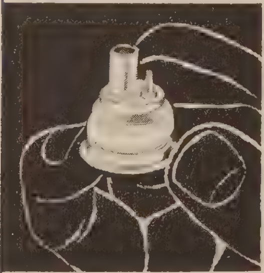
SEAL PROBLEMS? A CASE IN POINT



PROBLEM:
GENERAL ELECTRIC required development of a rugged compact high current hermetic seal CONTROLLED RECTIFIER housing constructed of materials and processes to withstand temperatures above soft solder range—design involves 5 seals to dissimilar materials.

SOLUTION:
Mechanical requirement dictated use of 3 metals: alloy #52, OFHC and Gr "A" Ni. Braze material selected is above 1435°F. so that subsequent welding or brazing can be done without detrimental effect. Tapered seals eliminate costly ground ceramics.

CERAMIC TO METAL ASSEMBLIES BY MITRONICS ARE:
• More precise • More compact • More economical • More durable

Why struggle with metallizing problems when Mitronics' complete engineering facilities are at your disposal.

C. W. BURROWS JR.

Carl W. Burrows, Jr., (M'59), has been appointed director of headquarters sales at Stromberg-Carlson Division of General Dynamics Coporation, according to an announcement by Allan R. Shilts, vice president and general manager of the division.

Mr. Burrows comes to Stromberg-Carlson from Hoffman Electronics Corporation where he was associated with the military products division as director of headquarters sales. Prior to this he was with the Bendix-Pacific Division of Bendix Aviation Corporation.

From 1943 to 1955 he was on active duty with the Navy. For two and a half years during this time he served as an instructor at the U. S. Naval Postgraduate School, Monterey, Calif. in communications and anti-submarine warfare. He resigned from the Navy in 1955 as a lieutenant commander.

He attended Pasadena City College and was graduated from the U. S. Naval Academy at Annapolis, Md., in 1943. He is also a graduate of the communications course at the U. S. Naval Postgraduate School, Annapolis.

He is a member of the Institute of Aeronautical Sciences and the American Rocket Society.

❖

Solomon Charp (A'43–M'44–SM'50), has been appointed Manager of Navigation and Control Electronic Equipment for General Electric's Missile and Space Vehicle Department, Philadelphia, Pa.

He is responsible for three basic functions: investigation of complete navigation and control electronic systems; design and development of control components such as sensors and computers; and the design of electronic circuitry.

He joined the company in July, 1959, as a Consultant in radiation and data comparison and electronic systems. For eleven years previous to that he was a member of the research staff of The Franklin Institute.

A native of Jersey City, N. J., he attended public schools in Philadelphia. He graduated from the University of Pennsylvania, Philadelphia, in 1940 with the B.S. degree in Electrical Engineering and received the M.S. degree from that university in 1941.

He was an instructor and research associate at the University of Pennsylvania for seven years previous to joining

high frequency performance...at medium frequency prices

2N393

The Philco 2N393 Micro Alloy Transistor (MAT) has proved its complete reliability in millions of operating hours in every type of computer logic circuit up to 5 mc. It combines all the advantages of high frequency performance with low price. The 2N393 is easily designed into any logic circuit and offers the designer these important advantages:

- High beta
- Low saturation voltage
- High speed
- High V_{BE} rating
- Low I_{CO}
- Low hole storage time

When you can buy so much for so little . . . don't settle for less in *your* equipment.

The 2N393 is also available in a military version . . . Mil 5-19500/77A (Sig.C.)

Other Philco MATs to Meet Your Special Requirements:

2N1122 . . . with 11 volt rating
2N1122A . . . with 14 volt rating
2N1427 . . . with additional parameter control

For data sheets, write Department IR 560.

*Reg. U.S. Pat. Off.

Immediately available in quantities 1-999 from your local Philco Industrial Semiconductor Distributor.

He has conducted research in naval anti-aircraft fire control systems, electromechanics, statistical-type analogue computers, radar reflections, and radar guidance systems.

Mr. Charp is a member of Tau Beta Pi, Pi Mu Epsilon, Sigma Xi, the Research Society of America, and the AIEE. He is a member of the Executive Board of the Philadelphia Section of the AIEE and serves as Treasurer, 1960 International Solid State Circuits Conference.

❖

L. Berkley Davis (SM'53), has been elected a vice-president of the General Electric Company. He is general manager of the company's electronic components division which is made up principally of the Receiving Tube Department (Owensboro, Ky., also site of division headquarters); the Cathode Ray Tube Department (Syracuse, N. Y.); the Power Tube Department (Schenectady, N. Y.); and the Semiconductor Products Department (Syracuse, N. Y.)

L. B. Davis

He was born in Lewisport, Ky., October 27, 1911, and graduated from high school there. He attended the Engineering College of the University of Kentucky at Lexington, a member of the class of 1934.

After starting work in 1934 as an engineer with the former Ken-Rad Tube and Lamp Corporation in Owensboro, Ky., subsequent advancements placed him in charge of tube production engineering and brought him the position of chief engineer for the Ken-Rad Transmitting Tube Corporation. During World War II he became plant manager of the Owensboro Transmitting Tube operation. General Electric acquired the Ken-Rad tube facilities on January 2, 1945, and near the end of that year Mr. Davis was made manager of the Owensboro operations.

In December, 1949 he was appointed general manager of General Electric Receiving Tube operations, with headquarters in Owensboro. He became general manager of the newly-created Electronic Components Division of the General Electric Company in June, 1956, and retains this position with his appointment as a vice-president of the company.

❖

Warren C. Foin (S'53–A'54), has been promoted to the position of development engineer in the 7080 Engineering Department of Advanced Data Systems Development at the IBM Product Development Laboratory in Poughkeepsie, N. Y. He is now project manager, responsible for the design of the IBM 7080 Data Processing System.

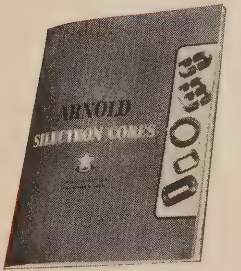
Arnold Pulse Transformer Cores are individually tested under actual pulse conditions

Here's technical data on

ARNOLD SILECTRON CORES



Bulletin SC-107 A . . . this newly-reprinted 52-page bulletin contains design information on Arnold Tape Cores wound from Silectron (grain-oriented silicon steel). It includes data on cut C and E cores, and uncut toroids and rectangular shapes. Sizes range from a fraction of an ounce to more than a hundred pounds, in standard tape thicknesses of 1, 2, 4 and 12 mils.

Cores are listed in the order of their power-handling capacity, to permit easier selection to fit your requirements, and curves showing the effect of impregnation on core material properties are included. A valuable addition to your engineering files—*write for your copy today.*

ADDRESS DEPT. P-5

The inset photograph above illustrates a special Arnold advantage: a 10-megawatt pulse-testing installation which enables us to test-prove pulse cores to an extent unequalled elsewhere in the industry.

For example, Arnold 1 mil Silectron "C" cores—supplied with a guaranteed minimum pulse permeability of 300—are tested at 0.25 microseconds, 1000 pulses per second, at a peak flux density of 2500 gausses. The 2 mil cores, with a guaranteed minimum pulse permeability of 600, receive standard tests at 2 microseconds, 400 pulses per second, at a peak flux density of 10,000 gausses.

The test equipment has a variable range which may enable us to make special tests duplicating the actual operating conditions of the transformer. The pulser permits tests at .05, .25, 2.0 and 10.0 microsecond pulse duration, at repetition rates varying anywhere from 50 to 1000 pulses per second.

This is just another of Arnold's facilities for better service on magnetic materials of all description. ● Let us supply *your* requirements. *The Arnold Engineering Company, Main Office & Plant, Marengo, Ill.*

When it comes to SEMICONDUCTORS

For the most **complete** line of solid state devices...

- Westinghouse has perfected the widest selection of rectifiers, transistors, and special semiconductor devices available in the industry. In Silicon power rectifiers, Westinghouse is the acknowledged leader in the field.

For the most **dependable** semiconductor devices...

- Every Westinghouse semiconductor device has been carefully designed, manufactured, and thoroughly tested to assure long life, high reliability, and excellent stability.

For **true voltage ratings** in silicon power transistors...

- Only Westinghouse 2N1015 and 2N1016 silicon power transistors offer *true* voltage ratings, guaranteed by 100% power testing—means they may be operated continuously at the V_{CE} listed provided the power dissipation of the transistor is not exceeded. Other conventional power transistors derate the V_{CE} voltage under comparable conditions.

For **new and unusual ideas** in semiconductors...

- Westinghouse is constantly pioneering in exciting new semiconductor devices. Among the latest: a new 50 ampere "TRINISTOR"* controlled rectifier; new thermoelectric cooling devices; an extremely rapid and sensitive infrared detector.

For quality, reliability, performance, and availability...

- Come to *Westinghouse!* For more information call your Westinghouse representative, or write directly to Westinghouse Electric Corp., Semiconductor Department, Youngwood, Pa.

YOU CAN BE SURE...IF IT'S Westinghouse

Westinghouse Semiconductor Department, Youngwood, Pa.

SAGE RESISTORS

with The Amazing New Moisture-Resistant

"IMPERVOHM" silicone coating

WHAT IS "IMPERVOHM"? . . . It is a new non-porous silicone encapsulant representing a significant moisture seal "break through," which has been developed exclusively for SAGE Characteristic "G" and "V" Power Resistors.

WHAT ARE ITS ADVANTAGES? . . . Because of its unusual characteristics attributed to optimum balance of resin and precise filler particles, this new coating requires no compromise in offering:

- Improved heat endurance (−65°C to +350°C).
- Superior resistance stability (0.1%) after severe moisture cycling.
- Availability of all type "S" Resistors as reliable body insulated styles (1000 Volts rms min.).
- New ruggedness in ultrasonic solvent wash not previously available.

These features signify an insulating achievement unmatched in the power resistor field.

WHERE DO SAGE "IMPERVOHM"-SEALED RESISTORS EXCEL? Component and Circuit Design Engineers will be wise to specify SAGE in all applications demanding critical sensitiveness to moisture and temperature extremes. They will also take advantage of the insulation ruggedness these Resistors offer for printed circuit assembly as well as for metal chassis contact mounting. Of special significance in all cases is long life environment protection.

YOU PAY NO PREMIUM FOR "IMPERVOHM" PROTECTION . . . This remarkable coating is now "Standard" on SAGE Resistors—conventionally wound types "S" and "CS" and non-inductively wound types "NS" and NCS."

AIRPAX

"500 SERIES" MINIATURE

CIRCUIT BREAKER

ACTUAL SIZE

AIRPAX
SERIES 500

POSITIVE PROTECTION

Available in series, shunt and relay types, Airpax Miniature Magnetic Circuit Breakers are stocked in DC, 60 and 400 CPS models. Current ratings are from 0.05 to 10 amperes. Trip action can be instantaneous or delayed depending on the circuit requirement. These Circuit Breakers are also available in 2 and 3 gang assemblies, in any combination, for interlock-circuit protection.

CAMBRIDGE DIVISION CAMBRIDGE, MARYLAND

(Continued from page 64A)

headquarters in Denver, Colo.

Since joining Martin in 1958, his major effort has been with the TITAN program. Martin is prime contractor for airframe design, fabrication and testing of the weapon system.

A leading guidance and control systems scientist, he was general manager of the Bendix Aviation Corporation's Research Laboratories Division, Detroit, before he came to Martin as research director. He became engineering director for the TITAN in January, 1959.

The new vice president founded the Dynamic Analysis and Control Laboratory at the Massachusetts Institute of Technology, where he was a faculty member for 13 years.

A native of Port Arthur, Texas, where he was born on June 27, 1914, Dr. Hall earned the B.S. degree in electrical engineering from Texas A. & M. in 1936. He received the M.S. degree in 1938 and the D.Sc. degree in 1943, both from M.I.T.

He joined the M.I.T. faculty in 1937 as associate professor of electrical engineering. He founded and became the first director of the Dynamic Analysis and Control Laboratory in 1946.

While at M.I.T., he helped to develop missile control design techniques and directed the control system design effort for the World War II BAT, the first successful Navy air-to-surface guided missile.

As laboratory director, he supervised the development of the first missile simulator. He also was a Martin consultant for the Navy VIKING high altitude research rocket.

He left M.I.T. in 1950 to become associate director of the Bendix Research Laboratories Division. He was named division technical director in 1952 and general manager two years later. At Bendix, he directed research and development of electronic and hydraulic controls, including guidance and control systems for several guided missiles and automatic machine tool controls.

He was a member of the first Automation Exchange group sent to Russia in 1955 under the auspices of the American Society of Mechanical Engineers.

Dr. Hall holds the Naval Ordnance Development Award and the Eta Kappa Nu Outstanding Young Electrical Engineer Award. He is a member of Tau Beta Pi, Sigma Xi and several engineering societies.

⁂

Cecil S. Bidlack (A'35–VA'39–SM'55), of Smith Electronics, Inc. and formerly of the National Association of Educational Broadcasters has joined the firm of Carl E. Smith Consulting Radio Engineers, Brecksville, Ohio. He will be responsible for consulting work in Television and FM broadcast.

His last assignment was with the sister firm of Smith Electronics, Inc., where as

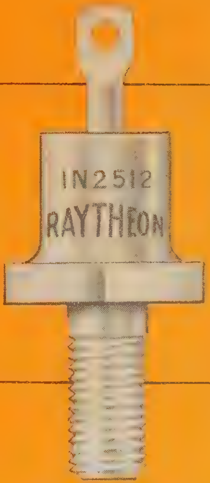
1N536
RAYTHEON

LOW POWER. Consider the high-efficiency Raytheon 1N536 series.



MEDIUM POWER. Look into the Raytheon 1N253 and the new 1N2512 series.

Raytheon diffused junction (upper photo) gives utmost uniformity, highest performance, greatest reliability. Compare with irregular fusion junction (below).

HIGH POWER. Note the all-new Raytheon 1N248A, 1N1191A and 1N1195 series.

For reliable power . . .

Depend on diffused junction rectifiers!

Here are reliable Raytheon diffused junction silicon rectifiers spanning the complete semiconductor power spectrum!

Raytheon manufacturing success in diffused junction rectifiers has long provided fast recovery, low forward voltage drop and extreme uniformity of device characteristics. Outstanding mechanical design and production under stringent quality control result in rectifiers with excellent ratings and characteristics. Utmost reliability is assured by constant life and environmental testing beyond the most stringent requirements of Mil 19500B, over the guaranteed temperature range of −65°C. to +165°C.

Of special interest in low current applications of the 1N536 series are the excellent reverse recovery, fast start and fast rise of Raytheon diffused junction rectifiers.

In the four amp range, the Raytheon 1N2512 series features low reverse current and is available in three package styles: with insulated stud, stud connected to anode, or stud connected to cathode.

In the higher current range, the new Raytheon diffused junction silicon rectifiers offer ratings up to 22 amps (at 150°C.)—plus the important advantages of low forward voltage drop and high efficiency, for exceptional regulation in power applications.

Further information on all these reliable Raytheon rectifiers is given on the following page. Semiconductor Division, Raytheon Company, 215 First Avenue, Needham Heights 94, Massachusetts.

Output wave shapes under varying input and load conditions. Sola Catalog No. 23-13-150 used in this test.

Sola's moderate-cost static-magnetic voltage regulator has sine-wave output

Sola now offers sinusoidal output in every standard-type regulator *with no price premium.* This development — a result of major design and production innovations — greatly widens the field of use for static-magnetic voltage regulation. The new standard sinusoidal design is now ideal for use with electrical and electronic equipment requiring a regulated input voltage with commercial sine wave shape — especially where harmonic-free supply had previously been too costly. The sinusoidal output also contributes to ease of selection and ordering, since this Sola stabilizer is virtually universal in application.

The Sola Standard Sinusoidal Constant Voltage Transformer provides output with less than 3% rms harmonic content. It automatically and continuously regulates output voltage within ±1% for line voltage variations of ±15%. Average response time is 1.5 cycles or less. The new line includes nine stock output ratings from 60va to 7500va.

Besides the improved electrical characteristics, these units are substantially smaller and lighter than previous models. Size and weight reductions were accomplished without any loss of performance or dependability.

With the Sola Standard Sinusoidal Constant Voltage Transformer you also get all the proved benefits of a static-magnetic regulator. It is simple and rugged. There are no tubes . . . no moving parts . . . no replaceable parts. Maintenance and manual adjustment are not necessary.

Its current-limiting characteristic protects against shorts on the load circuit. It is available in step-up and step-down ratios, allowing substitution for conventional, non-regulating transformers. These units can be used in any electronic or electrical application requiring a regulated sinusoidal power source where the peak power demand does not exceed the capacity of the constant voltage transformer. Circuit design formulae based on sinusoidal wave shape are directly applicable. Custom units to specific requirements are available in production quantities.

CLIMATE CONTROL EXPERIENCE:

PRESSURIZATION and DEHYDRATION

Look to Eastern Industries for the advanced pressurization/dehydration packs required by the avionic and ground support systems of tomorrow. Whenever a precisely controlled flow of dehydrated air is required, Eastern design and production experience team up to create compact, lightweight, reliable subsystems. Characteristics and performance range of existing units:

Characteristics and performance range of existing units:

capacities: up to 1.5 FT^3/Min. free air

operating temperatures: from −67°F to +150°F, 100% R.H.

operating altitudes: from 10,000 ft. to 50,000 ft.

weights: from 8 lbs. to 115 lbs. complete

Smaller packs feature replaceable chemical dehydrator elements — the larger subsystems are available with automatic reactivating dehydrators.

Let us quote on your next pressurization/dehydration requirement. In the meantime, write for full information on the entire line of Eastern aviation products. Send for Bulletin 360.

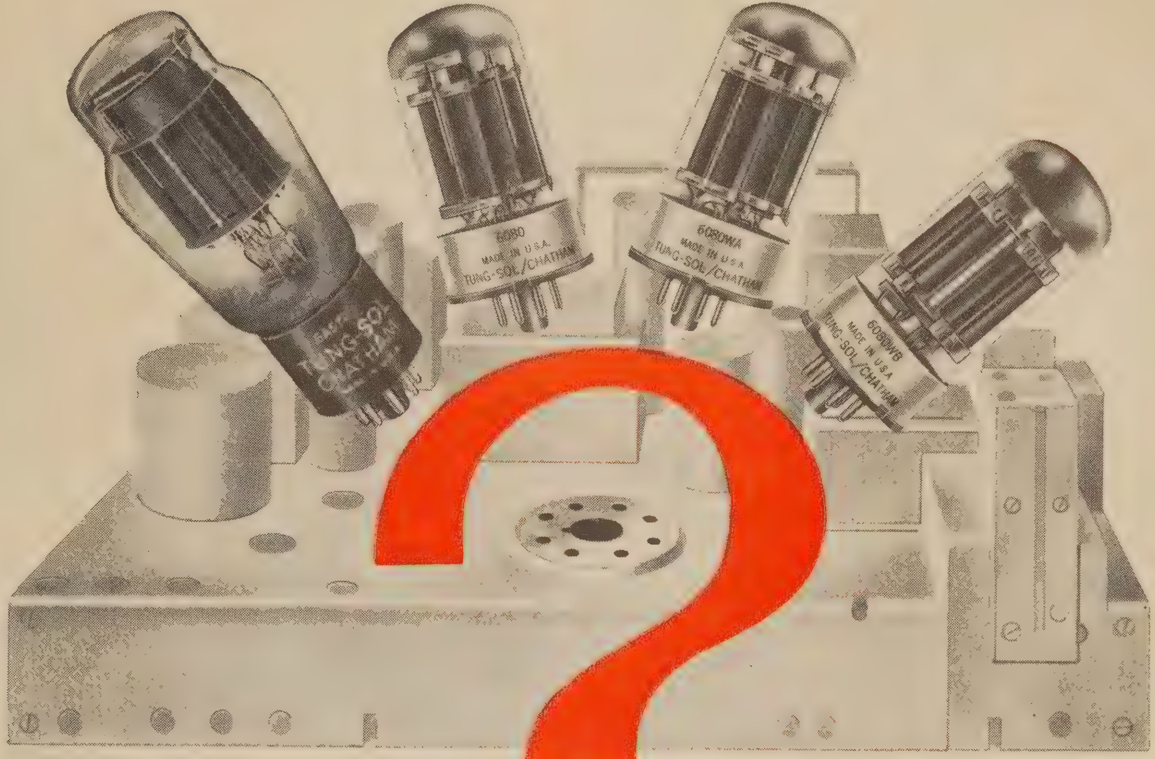
TUNG-SOL/CHATHAM 6080 FAMILY

All fit the same socket . . .



But which fits ? your application

Like most circuit designers, you're probably often confronted with a wide choice of tubes which meet the *electrical requirements* specified by your design. But depending on other factors, such as the kind of environment in which the tubes are expected to operate, your choice may be limited.

Consider the Tung-Sol/Chatham 6080 tube family, for example. The 6080, the 6080WA, the 6080WB and the prototype 6AS7G all fit the same socket. The electrical ratings of these series regulator tubes are the same. Would you know which to specify for your power supply? The differences are vital. Knowing them can make all the difference in the ultimate reliability of your design.

If economy in original component cost is paramount and size not a factor, then the 6AS7G may be your choice. If size is a factor, the smaller 6080 would be used. The 6080WA is the right tube if more closely controlled characteristics are important, if environmental conditions are severe, and if greater assurance of long life is needed. Where the tube is expected to operate under high ambient temperatures and severe vibration, and if many tubes are to be operated in parallel, then the 6080WB is best.

Of this you can be sure: Tung-Sol will recommend the "best" tube for your particular requirements. Once you have specified a Tung-Sol tube for your application, you'll be gratified by the superior performance and the highest operational reliability all Tung-Sol components provide. Every Tung-Sol tube is the product of the highest manufacturing standards and unexcelled quality control.

Full technical details on the Tung-Sol/Chatham 6080 family are also available to you on request.

And if you would like prompt and able assistance in selecting the correct tube for your application, get in touch with Tung-Sol tube experts. They'll be glad to study your design and recommend the tubes best for you. Tung-Sol Electric Inc., Newark 4, N. J. TWX:NK193

Technical assistance is available through the following sales offices: Atlanta, Ga.; Columbus, Ohio; Culver City, Calif.; Dallas, Texas; Denver, Colo.; Detroit, Mich.; Irvington, N. J.; Melrose Park, Ill.; Newark, N. J.; Philadelphia, Pa.; Seattle, Wash. Canada: Toronto, Ontario.

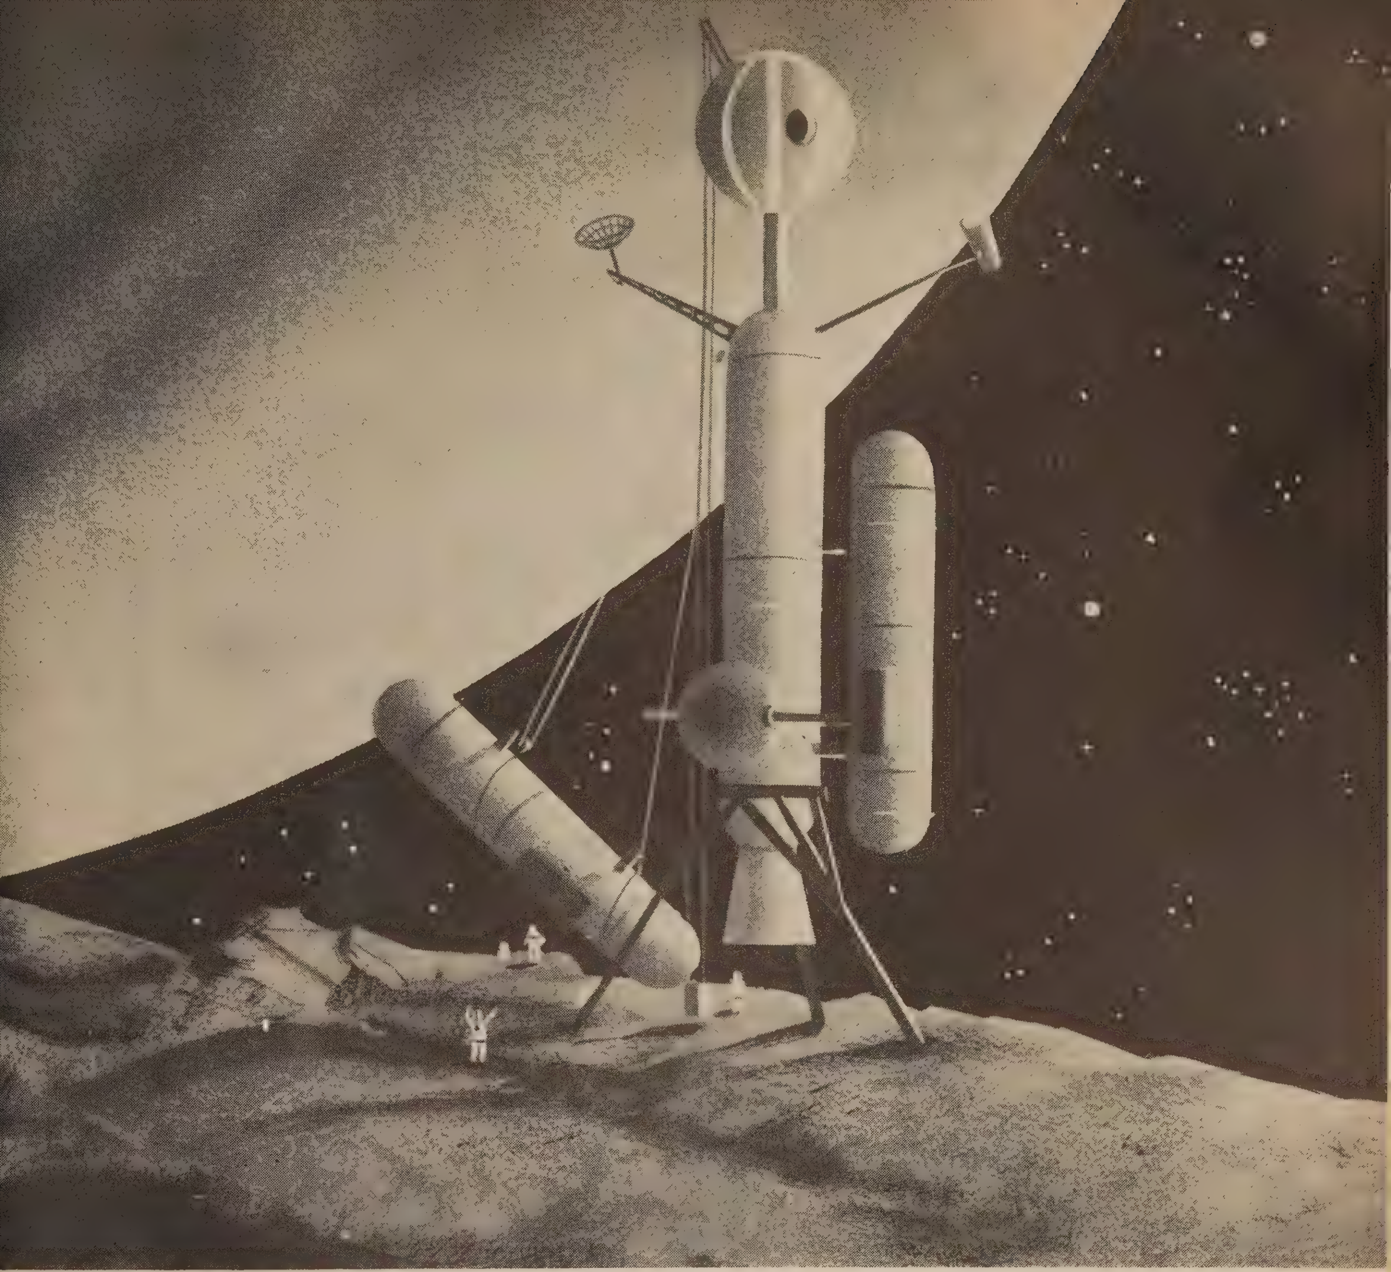
Here is Francis Alterman, Manager of General Mills Digital Computer Laboratory, checking one of our newest computers which he helped design. General Mills computers, both analog and digital, are being used in missile guidance, bombing and navigation systems, automatic surveying and in industrial control. In future space travel, computers will help control navigational systems of space vehicles and will process data gathered in outer space.

General Mills engineers work today

General Mills has been producing computers for nearly 20 years. Exciting new concepts in high speed magnetic tape units, ultra-high precision analog to digital converters and optical keyboards are examples of continuous developments in our over-all computer program. We work to improve reliability, increase speed, cut cost.

Our research activities cover broad areas in physics, chemistry, mechanics, electronics and mathematics. Some of the studies representative of these activities are: ions in vacuum, deuterium sputtering, dust erosion, magnetic materials, stress measurements, surface friction and phenomena, trajectory data and infrared surveillance.

In our engineering department, current projects include: specialized inflatable vehicles and structures, airborne early warning systems, micro wave radar test equipment,



Mars seen from one of its moons . . . illustration from book written for General Mills by Willy Ley.

to help you explore space tomorrow

antennas and pedestals, infrared and optics, inertial guidance and navigation, digital computers—and many other activities.

Our entire manufacturing department is geared to produce systems, sub-systems and assemblies to the most stringent military requirements. Our people have a wealth of experience in complex military projects.

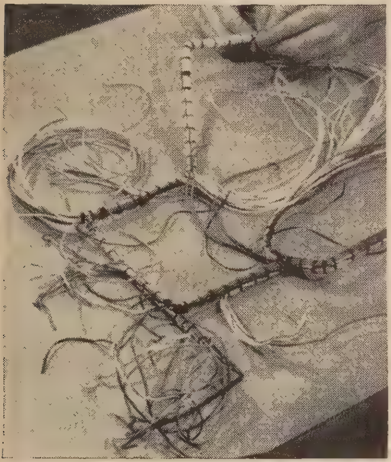
GUDELACE
is engineered for problem-free lacing



It's no accident that Gudelace is the best lacing tape you can buy. Excellence is *engineered* into Gudelace. A sturdy nylon mesh is meticulously combined with the optimum amount of special microcrystalline wax. Careful selection of raw materials and superior methods of combining them give Gudelace outstanding strength, toughness, and stability. Gudelace is the original *flat* lacing tape which distributes stress evenly over a wide area. It is engineered to stay flat; it will not stretch out of shape when pulled. Gudelace's nonskid surface prevents slipping, eliminating the too-tight pull that causes strangulation and cold flow. Durability and dependability make Gudelace your most economic buy—with no cut insulation, fingers, or feelings.

Write for Data Book with specifications on Gudelace and Gudebrod's com plete line of braided lacing tapes and dial cords—Temp-Lace, Stur-D-Lace, and Gude-Glass.

BALLANTINE'S MODEL 305A VOLTMETER

measures peak, or peak to peak

PULSES

as short as **0.5 μs**

AT PULSE RATES AS LOW AS 5 pps
...VOLTAGES OF 1 mv TO 1000 v

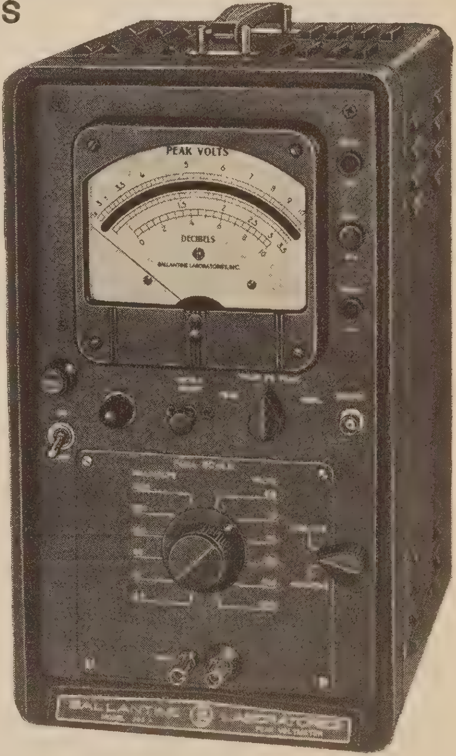
Also measures

Complex Waveforms
having fundamental of 5 cps to 500 kc with harmonics to 2 mc.

Accuracy
is 2% to 5% OF INDICATED VOLTAGE, depending upon waveform and frequency.

Scale
is the usual Ballantine log-voltage and linear db, individually hand-calibrated for optimum precision.

Input Impedance
is 2 meg, shunted by 10 pf to 25 pf.



Price: $395.

THIS "A" MODEL is the result of improvements and new features AFTER 11 YEARS OF MANUFACTURING THE VERY SUCCESSFUL MODEL 305

Write for brochure giving many more details

Engineering hints from Carborundum

Correct techniques simplify production of KOVAR® Alloy drawn shapes

KOVAR is an iron-nickel-cobalt alloy with thermal expansion characteristics essentially matching those of several hard glasses. It is the ideal material for making high-quality drawn shapes required for vacuum- or pressure-tight glass-to-metal seals in equipment such as electron tubes and semi-conductors.

KOVAR has deep drawing qualities similar to cold-rolled steel. Satisfactory results are assured by observing a few simple precautions:

1. On the initial draw, punch radius should be a minimum of four times the material thickness. Reduce successively on re-draws.
2. Inside radii at the corners on the final draw should be not less than the thickness of the metal.
3. Sharper radii, if absolutely essential, should be produced by a subsequent coining operation.
4. Hold-down pressures in drawing should be kept to a minimum to insure metal flow from the outside rather than stretching.

Obviously, to prolong tool life and simplify production, maximum permissible tolerances should be allowed. More detailed information on deep drawing of KOVAR alloy is supplied in Technical Data Bulletin 100 EB11.

Carborundum maintains large stocks of KOVAR alloy in a wide variety of sizes and forms. This alloy can be welded, brazed, soldered and plated with other metals. It can be either oxide bonded to hard glass or brazed to metallized-ceramic insulators. Technical service is available to help you solve processing and application problems. Contact The Carborundum Company, Refractories Division, Dept. P-50, Latrobe Plant, Latrobe, Pa.

Catching Up with a Slippery Equatio

What goes on when two moving surfaces are separated by a film of oil

Simple question? Maybe, but engineers and mathematicians have been trying to answer this classic question of lubrication ever since Osborne Reynolds neatly stated the problem in equation form back in 1

Unfortunately, analytical methods for solving Professor Reynolds' partial differential equation worked only for unrealistic oil bearings bearings with widths approaching zero or infinity. And approximate methods were crude, requiring a complete recalculation for each sligh change in the bearing.

Recently, mathematicians at the General Motors Research Laborato came up with the most versatile and efficient method of solution yet made. Their analytical method for solving the two-dimensiona Reynolds' equation applies to all finite journal bearings — as well a other hydrodynamic bearings — with *no* assumptions or approximatio about boundary locations. The new method uses a long-neglected en theorem recorded by Sir Horace Lamb instead of the force relationshi tried by Reynolds and others.

Besides being a valuable contribution to the theory of lubrication, thi work has its practical side: namely, accurate, serviceable design curves for engineers. At GM Research, we believe delving into both the theoretical and applied sides of a problem is important to progr It is a way of research that helps General Motors fulfill its pledge of "more and better things for more people."

General Motors Research Laboratories

Warren, Michigan

Hydrodynamic analyses have led to specific answers about bearing operation. Shown here are the oil pressure distribution (main illustration) and load-carrying capacity for a non-rotating journal with a reciprocating load.

Bendix Bulletin

Up-to-the-minute news about transistors

NEW DRIVER TRANSISTORS SWEEPING THE FIELD

Extra-versatile Bendix units beat high costs, design limitations over wide front

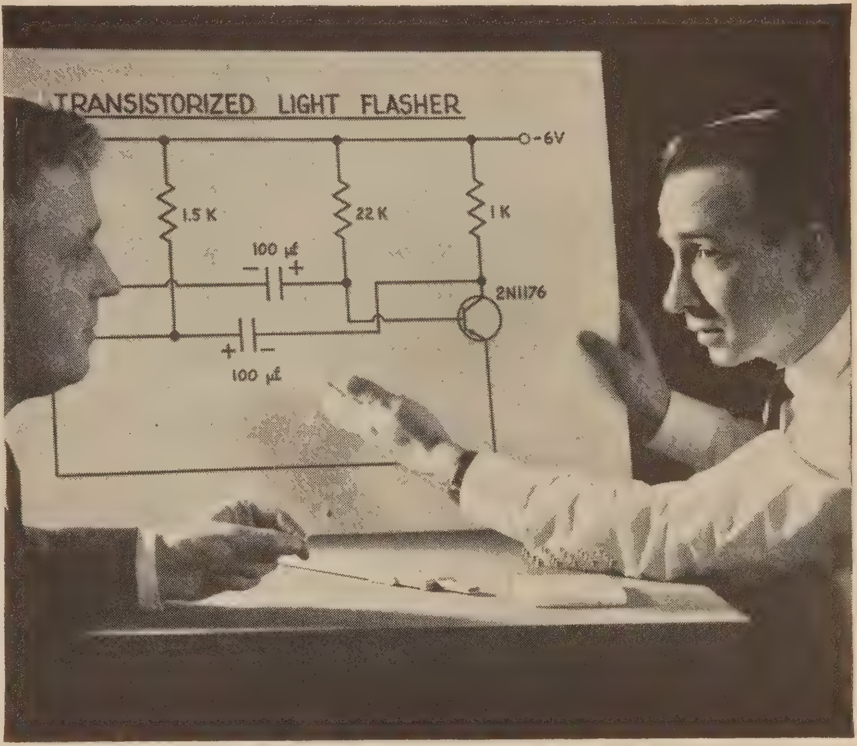
Called the "workhorse of the transistor industry," the new Bendix* Driver Transistor series is winning the nod from more and more engineers daily. These men find it the answer to audio frequency and switching applications requiring extra performance without extra cost.

Here is a special device for use where reliability, versatility, and low cost are primary requirements. The Bendix units combine higher voltage rating and high current gain with more linear current gain characteristics for low distortion and more efficient switching.

They're now in high production for rapid delivery in JEDEC TO-9 packages.

NEW BENDIX SEMICONDUCTOR CATALOG on our complete line of power transistors, power rectifiers, and driver transistors available on request. Write SEMICONDUCTOR PRODUCTS, BENDIX AVIATION CORPORATION, LONG BRANCH, N. J. For information about employment opportunities write personnel manager.

*TRADEMARK



ENGINEERS KNOW the new Bendix Driver Transistor line-up meets an unusually wide range of circuitry applications. Bendix Applications Engineering Department suggestions on circuitry problems are helpful, too.

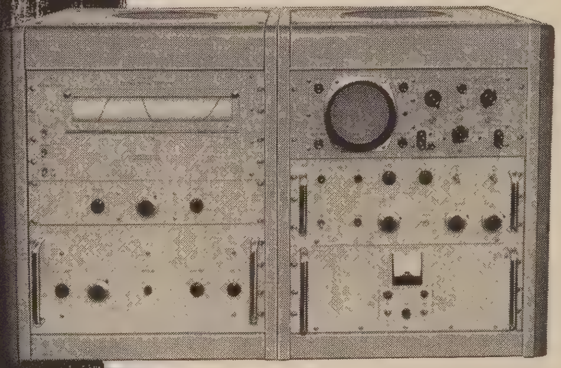
FOURIER INTEGRAL COMPUTER



Model CF-1

A sophisticated solution to the vexing problem of solving bounded Fourier integrals quickly and accurately, Scientific-Atlanta designed the Model CF-1 especially for the antenna design engineer.

The computer has broad general application including determination of the far fields of aperture antennas from the distribution of the field in the aperture, the far fields of arrays from the magnitude and phase of the currents in the elements, the frequency spectra of voltage pulses, and other physical problems involving Fourier transforms and their inverse transforms over finite limits.

PRICES

Model CF-1 Fourier Integral Computer . . . $9,000

Model APR 22 Antenna Pattern Recorder (logarithmic response) . . . $4,300

Consult your nearby S-A engineering representative for more information. Or you may write directly to the factory for complete specifications. Address Dept. 86.

A pulse transformer. Wire wound in careful coils. Metals, magnetic materials and dielectrics combined in careful ratios, spacings and dimensions. The result: a device with precise parameters—pulse shape, rise/fall times, ripple, backswing, overshoot, life. What sets this one apart? A unique thing—Carad capability. Capability gained in designing and building hundreds of special pulse transformer types to exact specifications. Weights from ounces to hundreds of pounds. Ratings from 10 volts to 500 kv. None of these extremes are considered limits at Carad. For pulse transformers of any type you will find it worth your while to investigate Carad capability.

CARAD CORPORATION 2850 Bay Road • Redwood City • California

Industrial Engineering Notes*

AIR TRAFFIC CONTROL

The Federal Aviation Agency hopes to have air traffic control on a semi-automatic basis by 1963 and fully automatic "as soon as possible thereafter," FAA Administrator E. R. Quesada said .Speaking at a meeting of the National Society of Professional Engineers, Mr. Quesada said a 400-engineer staff is working on R&D connected with modernization of the airways and that one of the most pressing projects is the automation of the air traffic control system. Automation has, he said, "terrifically far-reaching implications. The key to the project is the development of an air traffic control Data Processing Central that will remove many of the controller's bookkeeping chores and give him more time to analyze traffic situations and make control decisions." The Central's "most spectacular" function will be in probing, detecting, and predicting conflicts, he continued. It will warn of any unsafe situation and automatically suggest corrective alternatives. Present plans call for the Central to be controlling the New York, N. Y., area's air traffic in 1963, with systems to follow at Cleveland, Washington, Chicago, Los Angeles, and Oakland. Other plans for airway modernization call for increased installations of radar and other electronic equipment; improving the communications systems and the aeronautical weather service; and developing new control procedures, the administrator said.

ENGINEERING

Standards on resistors and capacitors have just been published by the American Standards Association. Publication 115 applies to fixed resistors of types other than wire-wound, with a rate dissipation not exceeding 2 watts and a rated resistance value between 10 ohms and 10 megohms, suitable for use in circuits where high stability properties are essential. Publication 116 applies to fixed capacitors with a dielectric of mica with the electrodes directly deposited on the mica sheets and intended for use in telecommunication receiving equipment and for similar applications in other electronic equipment. Copies of these publications are available from ASA Headquarters 70 E. 45th St. New York, N. Y., $3.20 per copy. . . . **A two-part report of Air Force-sponsored research into magnetic amplifier circuits has been published for sale to industry through the Office of Technical Services, U. S. Department of Commerce, Washington 25, D. C.**

MILITARY ELECTRONICS

The Army has shown members of the press a device which can, it was claimed, perform many of the functions of electronic devices—without electricity or moving parts. The device is a "pure fluid amplifier." The unit demonstrated by its inventors, scientists of the Army's Diamond Ordnance Fuze Laboratory in Washington, resembled a block somewhat larger than a pack of playing cards. It was airtight, except for tiny apertures, and contained passageways. Attached to a source of pressurized gas or liquid, the device can amplify, digitalize, remember, feedback, and compute, the scientists said. The new device "makes possible a whole new class of amplifiers, computers, logic circuits and control systems, and will bring automation and control more into industrial and personal life," its developers said. The "revolutionary" system will not replace the electronics industry, they declared, but in some specialized applications it "will do things better and more reliably than electronic systems." "Pure fluid amplifying and computing elements will take a place in hydraulic and pneumatic systems similar to the position that the vacuum tube and transistor occupy in the field of electricity," the scientists said. The amplifier works by injection into the internal passageways of one strong stream of gas or liquid and a second, weaker stream which displaces or redirects the main flow. The idea for the system is an old one—"an overlooked one," its developers said. Fluids in motion have been used in many applications, such as hydraulic systems, windshield wipers and autopilots. But those systems have moving parts. The advantage of the pure penumatic device is that it has none. Thus, the inventors claimed, it is trouble-free to an astonishing degree, easy to make and maintain, and as rugged as its few component materials are. It can operate, for example, in white heat. The inventors said a unit could be produced for 2/10ths of a cent which would do the work of a vacuum tube costing 50 cents. A unit the size of a pea with an aperture 5/1000ths of an inch in diameter was displayed. It was said that the size of the device could be adjusted to fit almost any applications "up into the horsepower range." The prime advantage is the speed of the device. "They will never compete with electronic systems for very high speed applications," the scientists said. The pure fluid amplifier will be described in an engineering handbook now being prepared by the Army and in a series of technical papers to appear in trade magazines. A full technical report will be issued later.

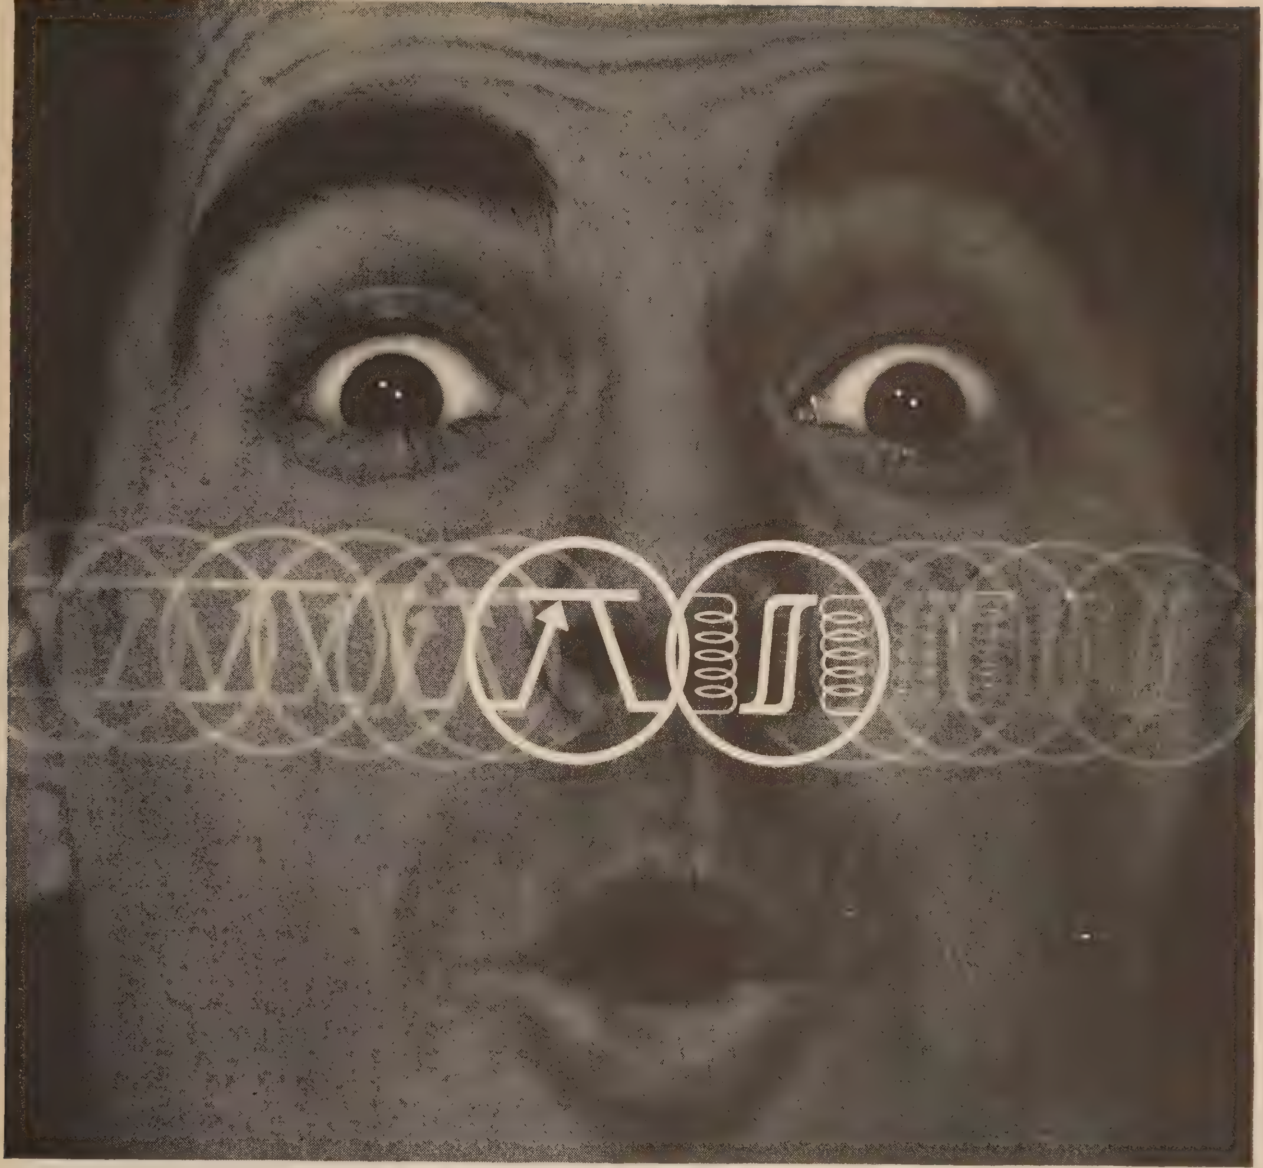
PUTTING MAGNETICS TO WORK



Open your eyes to new amplifier designs!

See how to combine tape wound cores and transistors for more versatile, lower-cost, smaller amplifiers

Tie tape wound cores and transistors into a magnetic-transistor amplifier, and open your eyes to new design opportunities.

To start with, these are static control elements—no moving parts, nothing to wear or burn out. Next thing you find is that you reduce components' size—your amplifier is smaller and costs less. That's because between them the core and the transistor perform just about every circuit function . . . and then some.

For instance? The core has multiple isolated windings. Thus you can feed many inputs to control the amplifier. The core also has a square hysteresis loop, and thus acts as a low loss transformer. That means you save power. In addition, the core can store and remember signals—so time delay becomes simple.

There's no need for temperature stabilization, either. The transistor acts only as a low loss, fast, static switch—and in this function it has no peer.

How do you want to use this superb combination? As a switching amplifier—or a linear one? In an oscillator? A power converter (d-c to d-c or d-c to a-c)? You'll have ideas of your own—and if they involve tape wound cores, why not write us? Ours are Performance-Guaranteed. *Magnetics Inc., Dept. P-81, Butler, Pennsylvania.*

EIA PROPOSAL

EIA has submitted to the Labor Department its proposed definition of the Electronic Equipment Industry and urged that it be used in the upcoming survey preliminary to a Walsh-Healey wage determination for the industry. The EIA proposal defines the industry in terms of classes of products it manufactures, and limits the categories to those that are specifically electronic. It is intended to replace a more general definition proposed earlier by the Labor Department which identifies the industry as devoted to ". . . the manufacture of electrical apparatus and sub-assemblies therefor involving the use of electronic tubes and/or solid state semiconductor devices." In a statement accompanying its definition, EIA pointed out that the proposal would eliminate the possibility of including products of other electronic industries already covered by Walsh-Healey wage determinations, such as the electronic components and the tube and semiconductor industries. The definition proposed by EIA is "The manufacture of electronic equipment for the purpose of this survey, is defined as that industry which manufactures any of the following classes of

An achievement in
defense electronics

NEW THERMOPLASTIC RECORDING DISPLAY ACHIEVES

Detection to Projection in Less than a Second

Large-screen display of radar signals can be recorded and projected in less than a second. This advanced technique in information display is an example of one application of the new thermoplastic recording system developed by General Electric.

The grainless, thermoplastic film eliminates processing delays and permits, with higher resolution, much greater enlargement than is practical with high-speed photographic film. Target delineation is also significantly improved by optical filtering used to increase the signal-to-noise ratio.

Now undergoing final development in General Electric's Electronics Laboratory, the "thermoplastic display" is expected to find maximum application in the high-speed radar systems of the future. 176-03

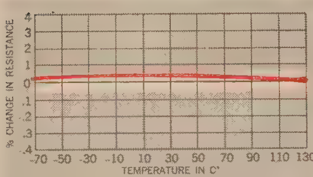
Time-tested!

— the time-tested standard of the resistor industry

Evanohm*

RESISTANCE ALLOY

— for resistors and precision instruments



Percent change in resistance of an ideal sample of Evanohm. Normal production material (.002" and finer) is supplied within the range ±10 ppm (−65° to 25°C. and 25° to 125°C, referred to 25°C.)

Wherever exceptional stability over a wide temperature range is essential, EVANOHM is the accepted standard of performance. This high-reliability resistance alloy provides high specific resistance, low temperature coefficient, low thermal EMF to copper. EVANOHM is especially recommended for use in resistors, aircraft instruments, for guided missiles, rockets and other precision equipment. Available in bare wire, enamel, formvar, polyurethane, silk, cotton, nylon and glass insulation. Write for complete electrical and mechanical data and recommendations on your specific application.

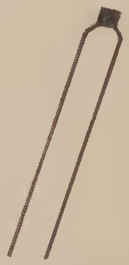
CERAMIC CAPACITORS

- Decimal dimensioned case
- Max. volumetric efficiency
- Contiguous flush-mount
- 47-10,000 mmf
- 200 vdc without derating
- −55°C to 150°C operation

"VK" capacitors are designed with square precision molded cases in only two sizes and a single standard 0.2" lead spacing for all values. Continuous life and environmental testing, plus 100% tests for Dissipation Factor, Insulation Resistance, and Capacitance guarantee that each "VK" capacitor in your circuit will perform as predicted.

ALSO UNCASED
FOR COMPLETE
ASSEMBLY
ENCAPSULATION



Same electrical characteristics as standard "VK" series. Each unit coated with a resilient protective compound. Dimensions: 47-100 mmf, .100" square; 120-270 mmf, .130" square; 330-1000 mmf, .150" square; 1200-3300 mmf, .250" square; 3900-10,000 mmf, .265" square.

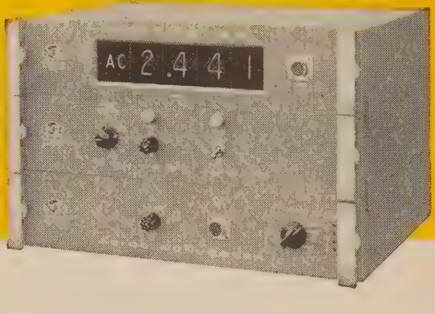
SIDE BY SIDE WITH ANY INSTRUMENTATION...



CUBIC Digital systems speak for themselves

An uncluttered, human-engineered front panel and internal engineering and construction demonstrate to the eye that Cubic's is the *superior* digital instrument. Proof of this superiority is in the *operation* . . . and side by side in independent evaluations of many instruments, Cubic again and again provides the instrumentation that is *specified*.

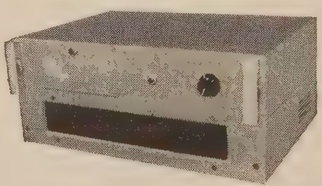
Any phenomenon of science which can be converted to a usable DC Voltage can be measured with the Cubic 4 or 5-digit Voltmeter (Models V-41, V-51) powered by the Model C-1 Control Unit. Addition of an AC Converter (Model AC-1, manual ranging; Model AC-2, automatic ranging) or a Model PA-1 Preamplifier extends the systems capabilities to the measurements of AC voltages or lower level DC voltages.

Precise resistance measurement is possible with the 0-41 and 0-51 4 and 5-digit Ohmmeters, powered by the C-1 or C-2 Control Unit.

Multiple input channels may be sampled rapidly and accurately with the Model MS-2, a single unit for scanning up to 100 points, or the MS-1, AS-1 Master-Auxiliary combination for scanning up to 1000 points with multiples of one, two, four or five-wire inputs.

Voltage ratio measurements are made with the R-41 and R-51 4 and 5-digit models operating only as Ratiometers or with the VR-41 and VR-51 models, which operate both as Ratiometers and Voltmeters. Measurements can be permanently recorded with the addition of a PC-Series Printer Control Unit, providing input for any quality printer on the market.

AND NEW FROM CUBIC . . . the Talking Meter, instrumentation that really *does* speak for itself, instrumentation that provides a new dimension in "readout," measurements or other parameters reported to the ear by a clear human voice.



Years-ahead engineering, factory production techniques inspired by pride in the end result, careful quality control and reliability testing . . . all these factors make Cubic's the truly fine instrumentation . . . Digital Systems that speak for themselves.

PRECISION Model 960

transistor and crystal diode tester . . .

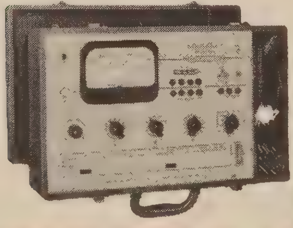
AND WHY IT WAS CHOSEN BY CURTISS-WRIGHT...

THE PROBLEM:

Curtiss-Wright needed an accurate and reliable transistor tester, for field testing and maintenance of their transistorized Propeller Synchronizer and its associated equipment.

THE SOLUTION:

After evaluating available test instruments, the ***PRECISION*** Model 960* was chosen on the basis of its design suitability, reliability and low unit cost.



*The Model 960 is a comprehensive test set designed for economical, practical and reliable checking of transistors and crystal diodes • specialized circuitry and operating parameters have been engineered in cooperation with leading semiconductor manufacturers • self contained AC power supply eliminates the necessity for batteries • $99.95

Perhaps you, too, have a production-line or servicing problem that can be solved by the ***PRECISION*** Model 960 . . .

If so, you will be interested to learn that the Model 960, and all other ***PRECISION*** test instruments, are available to you now for a free trial . . . in your plant . . . under actual operating conditions . . . without obligation.

For complete information . . . plus a copy of the comprehensive, new ***PRECISION*** test instrument catalog, write on your company letterhead to:

WHAT HAS THE **7182 S BAND MAGNETRON** IN COMMON WITH THIS CAT?

*

A good question! According to legend, a cat has nine lives—something that has yet to be proved. The 7182, on the other hand, has a *proved* life 8 to 10 times greater than any similar S-Band magnetron.

The 7182 retains its remarkable stability and reliability during a life of 10,000 hours, and is one of a series of magnetrons now in production providing peak powers of 5 MW. These magnetrons operate at voltages and current densities usually associated with magnetrons rated at a fraction of the power output.

A parallel development in L-Band ensures that attainments in this field equal the phenomenal successes already achieved with S-Band magnetrons.

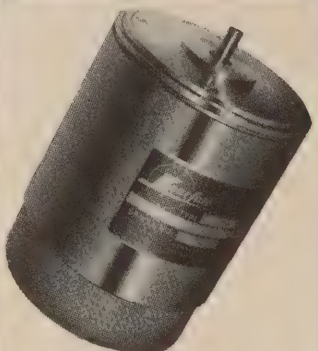
BASIC BUILDING BLOCKS FROM KEARFOTT



20 SECOND SYNCHRO

This synchro, just one of a broad line offered by Kearfott, provides the extreme accuracy required in today's data transmission systems. Kearfott synchro resolvers enable system designers to achieve unusual accuracy without the need for 2-speed servos and elaborate electronics. By proper impedance, matches up to 64 resolver control transformers can also operate from one resolver transmitter.

TYPICAL CHARACTERISTICS

	SIZE 25	
Type Resolver	Transmitter	Control Transformer
Part Number	Z5161-001	Z5151-003
Excit. Volts (Max.)	115	90
Frequency (cps)	400	400
Primary Imped.	400/80°	8500/80°
Secondary Imped.	260/80°	14000/80°
Transform. Ratio	.7826	1.278
Max. Error fr. E.Z.	20 seconds	20 seconds
Primary	Rotor	Stator

Write for complete data.

BASIC BUILDING BLOCKS FROM KEARFOTT

PRECISE ANGLE INDICATOR

Consisting of an angle position indicator, motor and servo amplifier, this small, versatile, rack panel mounted unit provides angular position indications for laboratory, production and field use. Input signals proportional to unknown angular position of synchro device being measured are resolved as an error voltage, which is amplified and used to drive an internal servo loop to null. Counter mechanism then provides direct visual readout of angular position.

TYPICAL CHARACTERISTICS

Input Signal: S_1, S_2, and S_3 of external synchro transmitter.

Repeatability: Within 0.6 minute in either a clockwise or counterclockwise direction for any angular position.

Readability: 0.5 minute through full range from zero to 360° Rotation is continuous.

Accuracy: ± 6 minutes in the standard unit. Other accuracies available on request.

Sensitivity: 0.5 minutes maximum.

Slewing Speed: Phase sensitive, 180° in 7 seconds.

Input Voltages: 115 volts, single phase, 400 cycles, 23 VA max.

Size: Standard Rack Mounting—1¾" x 9½" x 8½"

Write for complete data.

BASIC BUILDING BLOCKS FROM KEARFOTT

FLOATED RATE INTEGRATING GYROS

Specifically designed for missile applications, these Kearfott miniature gyros operate efficiently at unlimited altitudes. Their outstanding accuracy and performance make them superior to any comparably-sized units on the market. Hermetically sealed within a thermal jacket, these gyros are ruggedly designed and completely adaptable to production methods. Performance characteristics that are even more precise can be provided within the same dimensions.

TYPICAL CHARACTERISTICS

Mass Unbalance:
  Along Input Axis: 1.0°/hr maximum untrimmed

Standard Deviation (short term):
  Azimuth Position: 0.05°/hr
  Vertical Position: 0.03°/hr

Drift Rate Due to Anisoelasticity
  Steady Acceleration: .015°/hr./g^2 maximum

Vibratory Acceleration: .008°/hr./g^2 maximum

Damping:
  Ratio of input angle to output angle is 0.2

Characteristic Time: .0035 seconds or less

Weight: 0.7 lbs.

Warm-Up Time: 10 minutes from −60°F

Life: 1000 hours minimum

Write for complete data.

TOP LEVEL MEETING IN NATION'S CAPITAL

Washington, D.C., April 4 (AFCEA). The Armed Forces Communications and Electronics Association will hold its 14th National Convention and Exhibit in the nation's capital on May 24-26.

Because the Convention is a *common ground* meeting place, it affords you the perfect opportunity to get to know the most important members of the Services and

This bulletin is news for you if you're looking for big military contracts

The annual AFCEA National Convention and Exhibit really is a top level meeting, where you join the upper sales echelons as your own ambassador, and introduce your products in the most strategic of all areas.

Here you mingle with the cream of the electronics and communications industry, and the top representatives of the Armed Forces and government. Your firm and its products will be on display for a large, exclusive audience of market V.I.P.'s – all of whom are prospective customers.

Because the Convention is a *common ground* meeting place, it affords you the perfect opportunity to get to know the most important members of the Armed Services and your industry.

You meet with military purchasers and manufacturing colleagues; personal contact with those in the know keeps you up to date on the latest needs and projects of the military, as well as current industry research and developments.

The Exhibit is a must for manufacturers who want to sell in the most profitable of all markets. It serves as a big, bright showcase which attracts buyers from all over the country, and you as an exhibitor identify yourself in the most practical way as being a supplier in *the* market. Remember, almost all of the viewers of your display are prospective purchasers. A good, working display makes the contacts for you, and can mean on-the-spot sales!

The AFCEA Convention and Exhibit are both held in Washington's Sheraton-Park Hotel, where for three days you are kept busy and stimulated by:

> *Panel discussions* which feature carefully-prepared *professional papers* on timely military-electronics subjects, presented by well-known engineers and scientists.
>
> Interesting *speeches* on significant themes, given by famous military and industry personalities.
>
> A tour, conducted by the U.S. Army, through a large military installation.
>
> *Banquets, receptions* and *luncheons* which provide still more occasions for profitable contacts.
>
> And, of course, the 94 displays set up in the exhibition hall of the famous hotel.

"Communications and Electronics—the arm of control, the voice of command," is the theme of AFCEA's 1960 Convention and Exhibit. The Exhibit will reflect the amazing progress this young industry is making; wouldn't you like to show what your own firm has accomplished?

As a service to each exhibitor advertising in SIGNAL, the official publication of the AFCEA, a free ad in the exhibit listings of both SIGNAL and the official program is offered. Such wide advertising coverage gives added sales impact. The May issue of SIGNAL gives full coverage to the AFCEA Convention and Exhibit. In itself an "Exhibit in Print," this issue will be out in advance of the big event, spotlighting your products and serving to direct visitors to your display at the Exhibit. The issue will be indispensable as a guide to this year's Convention and Exhibit, since it will contain a complete list of exhibitors and the products to be displayed, as well as advance data about all technical papers, meetings, and other special activities.

For a complete and effective, year-round sales program that will make you a front-rank competitor in this $4 billion market, inquire about AFCEA's profitable package plan.

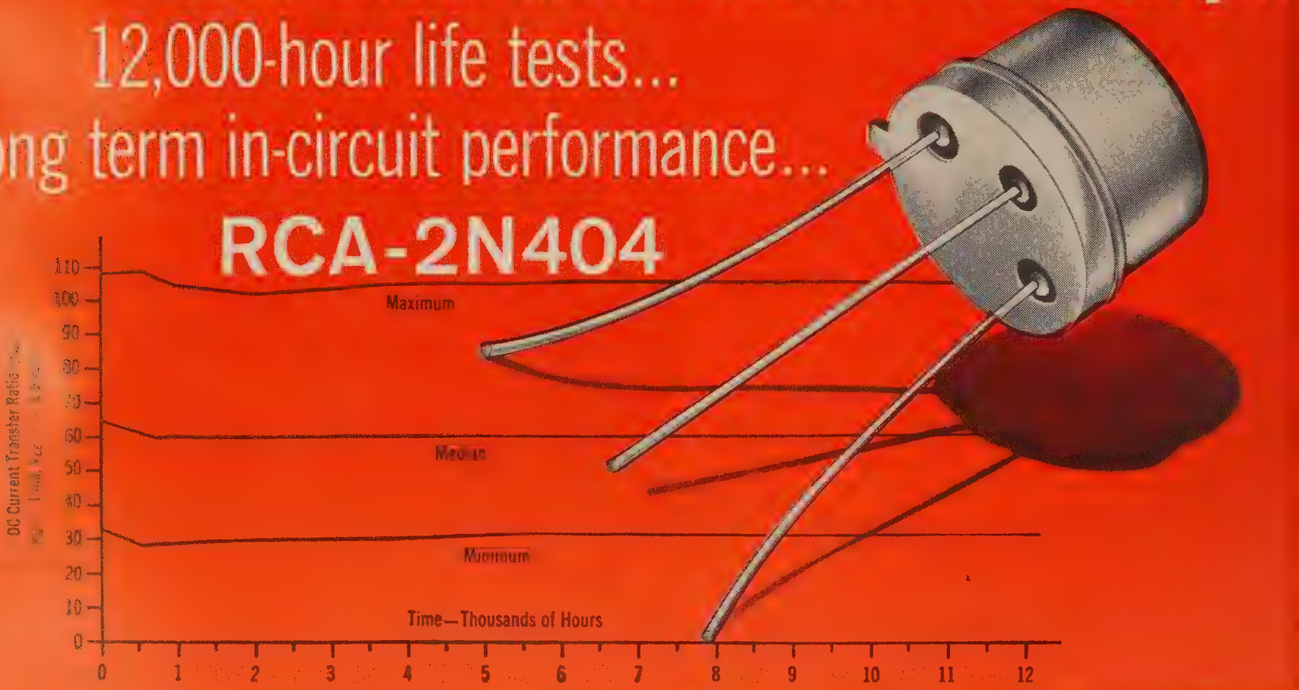
Now Check these Proofs of Reliability...

12,000-hour life tests...
long term in-circuit performance...

RCA-2N404



Variation in h_{FE} during a 35-mw life test at 55°C

The transistor that helped build an industry ...designed, built and introduced by RCA... chosen by top manufacturers for the finest computers...the RCA-2N404 has set new standards of reliability for transistorized computers

Outstanding new achievements of operating reliability, long life, and stability are being made by the RCA-2N404 germanium p-n-p medium-speed switching transistor. Stringent long-term life tests and dynamic in-circuit performance checks, both at maximum ratings, provide additional proof of the bedrock reliability of the RCA-2N404.

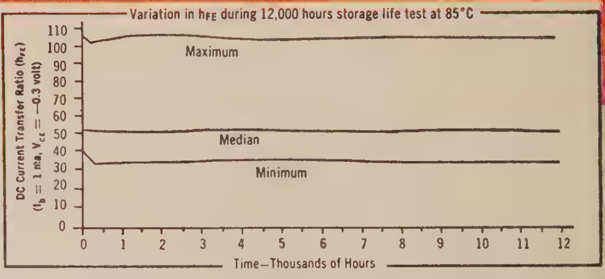
Here are the results:

(1) Representative samples of the RCA-2N404 computer transistor have now passed 12,000 hours of operating life at *maximum* ratings. The curves at the right show the remarkable stability of transistor parameters over this exceptional time period.

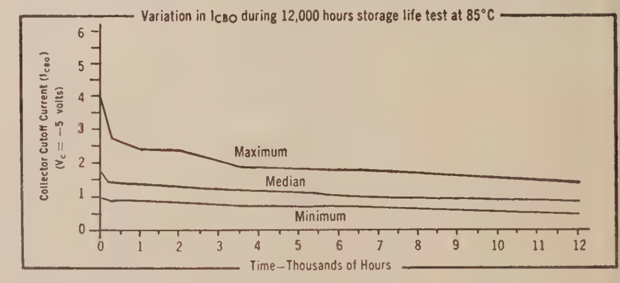
(2) Samples from every lot of RCA-2N404 transistors are tested at *maximum* ratings for 1,000 hours. During 1959, almost 6,000,000 transistor test-hours at 85°C junction temperature were logged.

Why not call your RCA Field Representative today for the full story on the RCA-2N404 and the RCA-2N404 designed to meet military specification MIL-T-19500/20 USAF. For technical information write RCA Commercial Engineering, Section E-35-NN, Somerville, N.J.

Variation in h_{FE} during 12,000 hours storage life test at 85°C



Variation in I_{CBO} during 12,000 hours storage life test at 85°C



Variation in I_{CBO} during a 35-mw life test at 55°C

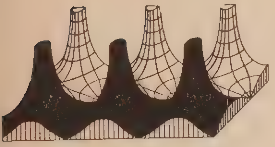
May, 1960
Vol. 48 No. 5

Proceedings of the IRE

Poles and Zeros



Section Publications. The issuance, in March, 1960, of a new edition of the "Manual for IRE Section Publications" recalls again the local Section phase of IRE "information processing." Poles and Zeros tossed a bouquet (Roses to Ye Editors) to the Section publications in April, 1959. It can now report a little over a year later, not only that old standbys are flourishing but also that two new infants are born. The new additions are the "Denshi Tokyo" and "The Benelux Bridge" of the Tokyo and Benelux Sections, respectively. We wish the newcomers well and trust that they will take their rightful place in the sun. Sections that contemplate a publication venture should acquire a copy of the Sections Publication Manual; it is filled with pertinent and helpful information.

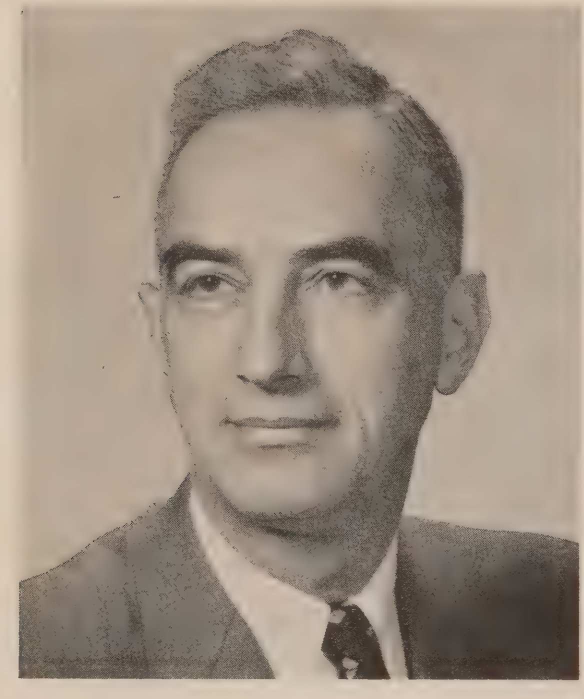
Feedback. The Editor of any publication receives mail from readers containing both constructive criticism, and destructive diatribe. Fortunately, the distribution of mail (to this Editor, so far) is weighted on the constructive side. Every etter has received, or is receiving, attention from the Editorial Board. Occasionally, the sequence of correspondence is in itself helpful. On two successive days letters were recently received. The first letter suggested that all issues of the PROCEEDINGS should be "Special Issues" and contain only material of general interest (twelve per year—what would we call them?). The same correspondent suggested that specific nterest material be published in the TRANSACTIONS. The second letter deplored the use and existence of the TRANSACTIONS and, the writer felt, all material should be published in the PROCEEDINGS. Perhaps the present plan is the compromise which meets the need of most people!

Another correspondent struck a most responsive chord. He made an impassioned plea for the use of a consistent set of dimensional units for all PROCEEDINGS papers. A glance through several issues of the PROCEEDINGS validates his protest. As engineering writers we are certainly careless about dimensionality. In a given paper, on occasion, the same author mixes the English and the metric systems. This carelessness does not contribute either to smooth reading or to ease of continuity of interpretation. Without entering into the larger question of the ultimate adoption of the metric system in the United States (see, for example, page 584 of the April, 1959 issue of the PROCEEDINGS), it does seem that at least for scientific and technical articles, uniformity would be advantageous. Since the MKS system has been officially adopted, and all college and university text books have accepted the system, why not use it consistently in all engineering writing?

Another letter to the Editor has pointed out certain inconsistencies, to be deplored, in the use of abbreviations. What excuse is there, queries this communicator, for the small case "m," as an example, in "mc" as an abbreviation for megacycle and in "ms" as an abbreviation for millisecond? This complaint recalls the interesting article by Arnold P. G. Peterson, in the TRANSACTIONS ON ENGINEERING WRITING AND SPEECH, for December, 1959, in which he suggests a rational system for naming the prefixes for both positive and negative powers of ten, and he associates with each a suggested symbol. These suggestions avoid the difficulty quoted above by using capital letters as symbols, for positive values of the exponent of ten, and lower case letter symbols for the negative exponent.

These rambling comments, engendered by recent correspondence, emphasize the necessity for such a Professional Group as that on Engineering Writing and Speech; it behooves all IRE authors to make use of the opportunities this Professional Group offers for the improvement of their literary efforts. The Editorial Board is presently considering the revision and subsequent reissuance of the IRE document titled "Information for Authors." This brief document might well be supplemented ultimately by a more complete "style manual" produced in cooperation with the PGEWS.

Aftermath. Poles and Zeros in March took notice of the 1960 International Convention and Radio Engineering Show. In those comments attention was called to the Panel Session "Electronics—Out of This World" and now that the convention is history one reflects that much of it was "out of this world." To this observer a small sample of such reflections might be listed thus: opening ceremonies at the Coliseum contacted Pioneer V, already 1,449,000 miles from earth and going away at the rate of 6,000 miles an hour; components so minute that their containers must be labeled "This Box Is Not Empty;" solar powered electric automobile (1912 model), which prior to the convention operated in Central Park; the announcement of a search for intelligence coming from outer space at distances so great that the initiators may have been extinct for milleniums; passive satellite balloons ten stories high; eyes and brains too tired to take in more; possible clues to the diagnosis of muscular disease based on new ability to measure extremely weak high frequency electrical signals; miracles of microminiaturization—a one hundred tube digital computer the size of a cigarette box; the implantation of electronic equipment in the human body for periods up to five years; the use of electronic devices for prenatal diagnosis; etc., etc.; the largest attendance of all time totaling 69,760, exceeding 1959 by 15 per cent.—F. H., Jr.



Ferdinand Hamburger, Jr.

Editor, 1960

Ferdinand Hamburger, Jr. (A'32–M'39–SM'43–F'53) was born in Baltimore, Md., on July 5, 1904. He received the degrees of Bachelor of Engineering in 1924, and Doctor of Engineering in 1931, from The Johns Hopkins University, Baltimore, Md. He was a Charles A. Coffin Fellow in 1930–1931.

During the period between the undergraduate and graduate degrees he participated in a program of dielectric research at The Johns Hopkins University. In 1931 he was appointed instructor in electrical engineering, in 1947 professor of electrical engineering, and in 1954 chairman of the Department of Electrical Engineering, and in addition, in 1958 Director of the Radiation Laboratory of The Johns Hopkins University. He served as chief test engineer for Bendix Radio Division from 1942 to 1945, while on partial leave of absence from the University. He has acted as consultant for the Research and Standard Section, Bureau of Ships, Navy Department; U. S. District Court; RCA, and others. He has served as Research Contract Director of a number of research investigations supported by the Department of Defense at The Johns Hopkins University.

Dr. Hamburger was IRE Regional Director of the Central Atlantic Region in 1950–1951, and a Director-at-Large in 1959. He has served on the Nominations, Appointments, Policy Advisory, and Education Committees. He has been a member of the Editorial Board since 1956 and was Vice Chairman in 1958–1959. He was IRE representative at The Johns Hopkins University from 1941 to 1955. He was largely responsible for the formation of the Baltimore Section of the IRE in 1939 and its reorganization in 1944; he served as its Chairman in 1940–1941.

He is a Fellow of the American Institute of Electrical Engineers and is presently serving as Vice Chairman of its Instrumentation Division. He is a member of Sigma Xi, Tau Beta Pi, and Eta Kappa Nu, and is a registered Professional Engineer in the State of Maryland.

Some Notes on the History of Parametric Transducers (Mumford, p. 848)—One would be hard put to name a subject which has caused more excitement in recent years than the parametric amplifier. What started as a small flurry of article writing a few years ago has since grown to near blizzard proportions. Well over 100 papers have been written on this subject in the last two years alone. Yet the parametric principle has been with us for many decades. Zenneck and Alexanderson described magnetic frequency doublers and magnetic amplifiers to IRE audiences 44 years ago. Indeed, this subject can be traced as far back as 1831 to Faraday's observations of the double period oscillation of surface waves of liquids. The history of the development of parametric principles and devices, from 1831 to the present, is briefly summarized in this excellent review of the subject. The chronology presented here, supported by 200 selected references, is little known and will do much to help readers orient in their minds the recent rash of new amplifiers having a common underlying principle.

Low-Noise Tunnel-Diode Down Converter Having Conversion Gain (Chang, *et al.*, p. 854)—A new and important use has been found for a device which is currently one of the most talked about components in the electronics field. As reported last July in the PROCEEDINGS, the tunnel, or Esaki, diode is a semiconductor device with negative resistance characteristics which give it exceptional high-frequency low-noise amplification capabilities. It is now shown that the nonlinearity of this negative resistance characteristic can be used for low-noise high-gain frequency conversion—from a high frequency to a lower frequency. This down-conversion capability is most significant. Although good up-converters have been developed recently, there is at present no mixer device capable of down-conversion that does not exhibit either a conversion loss or a poor noise factor. Thus the tunnel diode becomes the first device which can convert UHF or microwave signals to a lower frequency with low noise and conversion gain.

Noise Limitations to Resolving Power in Electronic Imaging (Coltman and Anderson, p. 858)—In recent years an increasingly large segment of the electronics profession has become concerned with the recognition of patterns on television and other cathode-ray-tube displays in the presence of noise. The study presented here of the limiting effects of noise on image resolution will be of fundamental interest to this group of readers. The authors show that the resolution limit can be accurately predicted in quantitative terms from a knowledge of noise power per unit bandwidth and the sine wave response of the system.

Packaged Tunable L-Band Maser System (Arams and Okwit, p. 866)—A maser normally requires cumbersome and highly precise supplementary equipment which limits its use to laboratory and a few other special types of installations. This paper describes a tunable maser system that has been packaged into a sufficiently compact form to make it suitable for field operational use without detriment to its low-noise performance. This "reduction to practice" of one of the important new developments in electronics will be of wide interest, especially to radio astronomers because its frequency range makes it suitable for studying the Doppler shift of the 21-centimeter hydrogen line in receding galaxies.

Cadmium Sulfide Field Effect Phototransistor (Bockemuehl, p. 875)—Cadmium sulfide has previously achieved fame as a photoconductive material. The author has now extended its utility by fabricating a cadmium sulfide transistor and obtaining useful power gain from it. This represents the first time that field effect amplification has been reported for any material in which virtually all the carriers are generated photoelectrically. Although CdS will never compete with germanium for general transistor applications, this work opens the door to many novel photocircuit functions which are not practicable with conventional circuit elements.

The Optimum Formula for the Gain of a Flow Graph, or a Single Derivation of Coates' Formula (Desoer, p. 883)—During the seven years since the first paper on the subject appeared in the PROCEEDINGS, signal flow graphs have become a popular and useful tool for analyzing a wide variety of engineering problems. This paper provides an important refinement of this tool—a new and simpler derivation of the gain formula for flow graphs. It has the added blessings of being a self-contained discussion of the subject and, in the author's words, being so simple "that even seniors can grasp it."

A Broad-Band Cyclotron Resonance RF Detector Tube (Turner, p. 890)—A novel method of detecting RF signals has been developed which utilizes the spiral motion of electrons as a tunable system which will become resonant when the frequency of spiraling is the same as that of an incoming signal. The tube is in essence a complete TRF receiver (less video amplifier) within one vacuum envelope. Its rapidly variable tuning and wide bandwidth (10 to 1) will make this development of considerable interest to engineers concerned with microwave systems for search, analysis and reception of signals over wide frequency ranges.

Anomalies in the Absorption of Radio Waves by Atmospheric Gases (Straiton and Tolbert, p. 898)—This paper will be of great interest to anyone concerned with propagation above 10,000 megacycles. The authors have gathered the results of recent propagation measurements in the millimeter range to shed new light on losses due to atmospheric absorption. They find that the measured losses in this relatively new part of the spectrum do not entirely agree with the losses predicted by classical theory developed over a decade ago, especially with respect to losses due to water vapor.

Interaction Impedance Measurements by Propagation Constant Perturbation (McIsaac and Wang, p. 904)—This paper is concerned with a technique for measuring the interaction impedance characteristics of microwave circuits by determining the change produced in the propagation constant when a rod is inserted in a waveguide. The technique is broadly applicable to various types of microwave structures, such as slow wave structures for traveling-wave tubes, and the results developed here will no doubt be regarded as a primary reference on the subject.

Taylor-Cauchy Transforms for Analysis of a Class of Nonlinear Systems (Ku, Wolf and Dietz, p. 912)—Since this paper is a companion to the paper that follows, the discussion of both papers have been combined below.

Laurent-Cauchy Transforms for Analysis of Linear Systems Described by Differential-Difference and Sum Equations (Ku and Wolf, p. 923)—This and the companion paper that precedes it describe a novel type of transform for solving problems described by linear and nonlinear differential and difference equations. The first paper, on Taylor-Cauchy transforms, deals with continuous nonlinear processes, while the second paper, on Laurent-Cauchy transforms, deals with discrete processes. They provide engineers with another tool of considerable usefulness in the analysis of a variety of physical systems.

Scanning the Transactions appears on page 965.

Some Notes on the History of Parametric Transducers*

W. W. MUMFORD†, FELLOW, IRE

Summary—**This paper summarizes briefly the chronology of the development of parametric transducers. The early works of Michael Faraday (1831), F. Melde (1859), and Lord Rayleigh (1883) are cited as mechanical examples and the pioneering work of L. Kühn, J. Zenneck, E. F. W. Alexanderson and R. V. L. Hartley are cited as electrical examples. A very brief résumé of selected contributions follows, dating from the work on H. Q. North's diodes in 1945 to the present flurry of excitement beginning in 1954, created by the development of the Signal Corps-Bell Laboratories Task 8 varactor diodes. A list of 200 selected references is included.**

THE recent interest in amplifiers which derive their gain from variable reactance circuit elements stems chiefly from the development of low-loss variable-capacitance diodes. There are two reasons for this interest. One reason is the fact that such amplifiers have low noise and the other is that the diodes are expected to have extremely long life. Either one of these properties is adequate justification for the excitement currently rampant throughout the world concerning the exploitation of this "new" type of amplifier, but, with two good reasons readily apparent, this excitation is doubled.

Mystery seemed to invade the thoughts of people when the scientists announced this new type of amplifier which was called a variety of names, such as: "Parametric Amplifier," "Reactance Amplifier" and "MAVAR" (Modulator Amplifier by Variable Reactance).[1] Some of this mystery could have been avoided had the modern men known or mentioned that the principle underlying the mechanism whereby electrical amplification was effected was an old principle. This principle may be broadly stated thus: *The energy of an oscillating system may be increased by supplying energy at a frequency which differs from the fundamental frequency of the oscillator.* One mechanical illustration of this principle is the simple pendulum. The child in the swing learns that he can "pump up" the amplitude of the oscillation of the swing by lowering his center of gravity on the down swing and raising it on the up swing. He thus "pumps" at twice the frequency of the swing. Who knows when this was invented? Could it have been in prehistoric times by a monkey swinging by his tail from the branch of a tree?

Faraday, Melde and Lord Rayleigh have published observations and calculations concerning this principle. Quoting Lord Rayleigh, "Faraday, . . . with great ingenuity and success (upon examining) . . . the crispations upon the surface of water which oscillates vertically, arrived at the conclusion experimentally that there were two complete vibrations of the support for each complete vibration of the liquid. Crispations (may be) observed upon the surface of liquid in a large wine glass or finger glass which is caused to vibrate in the usual manner by carrying the moistened finger round the circumference. All that is essential to the production of crispations is that the body of liquid with a free surface be constrained to execute a vertical vibration. Faraday's assertion that the waves have a period double that of the support has been disputed, but it may be verified in various ways." Faraday's work was published in 1831 and Lord Rayleigh verified his conclusions sixty years later, also with considerable ingenuity. The double period oscillation of the water is not readily proven by casual observation.

The following example of the principle, reported by Melde in 1859, is, however, readily observed and understood. Quoting again from Lord Rayleigh, "Perhaps the best known example is that form of Melde's experiment in which a fine string is maintained in transverse vibration by connecting one of its extremities with a vibrating prong of a massive tuning fork, *the direction of motion of the point of attachment being parallel to the length of the string.* Under these circumstances . . . the string may settle down into a permanent and vigorous vibration, whose period is the *double* of that of the fork." Lord Rayleigh analyzed and experimented with this and other similar mechanical phenomena in 1887. This led to analogous experiments with electrical circuits.

The electrical principle is readily understood by the following simple explanation. Suppose that we have a capacitor formed by two metal plates separated by air. Assume that a charge exists on the capacitor. The plates will be attracted to each other because of the equal and opposite charges so that to separate the plates requires work. Upon separating the plates, say to twice the original distance, the capacitance will be reduced to half its original value and, hence, the voltage must be twice the original value, since the charge upon the plates remains the same. The electrostatic energy, however, has been doubled, since it is proportional to the square of the voltage and directly proportional to the capacitance. The energy required to separate the plates now appears as electrostatic energy in the capacitor.

Now suppose that the capacitor is combined with an inductor to form an oscillating circuit. The voltage on the capacitor will reach a maximum value twice each cycle. Now if, on each half cycle, the capacitance is decreased when the voltage is maximum and increased when the voltage is zero, net energy will be imparted to the oscillations since no electrical energy is used to restore the capacitor to its original value when the voltage is zero.

---

* Original manuscript received by the IRE, November 17, 1959; revised manuscript received, February 1, 1960.

† Bell Telephone Labs., Whippany, N. J.

[1] These three names are considered herein to be synonymous and to apply to any device which derives its gain from the pumping of a variable reactance.

Similarly, it is apparent that energy could be imparted to the circuit had the *inductance* been varied in the appropriate phase. This electrical principle was expanded to include frequencies other than the two-to-one ratio and the resulting device was used successfully in radio telephone communication between Berlin and Vienna prior to World War I. This was described by L. Kühn in 1915. Prof. J. Zenneck, E. F. W. Alexanderson and R. V. L. Hartley pioneered with theoretical and experimental contributions within the next few years. Alexanderson called these devices "Magnetic Amplifiers," a name which remains with us today. The objective then was to modulate a continuous wave arc transmitter by means of a nonlinear inductance or saturable reactance. Here the voice currents constituted the signal, and the carrier was the pump. The resulting sidebands were radiated, together with the pump (or its harmonic in some cases).

I quote the following from a paper delivered by E. F. W. Alexanderson at an IRE meeting in New York City on February 2, 1916:

> The name "Magnetic Amplifier" has been given to a device for controlling the flow of radio frequency currents because this name seems to describe its function when it is used for radio telephony better than would any other. As the same device can be used for a variety of other purposes, the above name may in some cases not seem too appropriate. However, the essential part of the theory that will be given refers to the amount of amplification which is possible of attainment and the methods of securing a higher ratio of amplification than would be given by the device in its simplest form. . . .
>
> The ratio of amplification is proportional to the ratio between the frequency of the radio current and that of the controlling current.

(This conclusion was verified by R. V. L. Hartley and subsequently by Manley and Rowe.)

Alexanderson, in the discussion, also suggested amplification of incoming signals by cascaded stages of up-conversion, rectification and up-conversion, etc. The name of Alexanderson's device withstood the rigors of time. Currently, however, we recognize its radio frequency version as a type of parametric amplifier, reactance amplifier, or MAVAR.

In Alexanderson's magnetic amplifier, the chief interest resided in the mode of operation in which the input signal was in the voice frequency band and the useful output power was taken in some radio frequency band. Thus it was a modulator or up-converter.

Alexanderson presented curves to show that negative resistance effects could exist. Quoting again from his 1916 paper: Under some conditions "instability and generation of self-excited oscillations" can exist. "This is a condition that must be avoided for telephone control; whereas it may have useful applications for other purposes." (One useful application, pointed out by Eugene Peterson in 1930, was the negative resistance straight-through amplifier, in which the negative resistance effect was enhanced by the suppression of frequencies higher than the pumping frequency.)

Louis Cohen, in a communicated discussion of the paper, said:

> It appears to me that the fundamental principle . . . will find its application to other problems in connection with radio frequency circuits. One that suggests itself immediately is the amplification of incoming signals.

Alfred N. Goldsmith pointed out the advantages of Alexanderson's magnetic amplifier over the direct-current-controlled frequency doubler employed by Kühn.

Lee De Forest commented that the magnetic amplifier was far more practical as a high-power modulator than the ensemble of over 500 audion amplifiers used to obtain 11 kw at Arlington by the Western Electric Company. "No one can say, however, that the situation will not be altered very materially in one, two or three years after we learn how to build oscillions for large power outputs, say 5 or 10 kw each. That will create a very different situation."

Thus, there appears to be very old prior art on MAVAR, both as modulator and amplifier. However, the interest in magnetic amplifiers as radio frequency modulators subsided quickly with the advent of the high-power vacuum tube modulators. The "different situation" predicted by Lee De Forest in February, 1916, did, indeed, come to pass.

In the 1920's and '30's, interest developed in subharmonic oscillations in electrical circuits containing a variable reactance. These "parametric" oscillations could exist at any one of f/n frequencies, where n is the subharmonic fraction of the fundamental frequency. In 1954 Von Neumann and Goto independently recognized that a phase ambiguity existed in the subharmonic oscillations and that this ambiguity could be utilized in logic circuits. Goto calls this device a "parametron."

About thirty years after the pioneering work of Kühn, Zenneck, Alexanderson, and Hartley on inductive reactance modulators, interest developed in capacitance reactance modulators at microwave frequencies. The failure of reciprocity in some crystal converters observed in the middle 1940's by L. Apker of General Electric Co., Schenectady, N. Y., and R. N. Smith of Purdue University, Lafayette, Inc., and the peculiar behavior of welded contact germanium diodes made by H. Q. North of General Electric Co., Schenectady, N. Y., was interpreted to mean that the contact capacity varied with bias. H. C. Torrey of the Massachusetts Institute of Technology Radiation Laboratory, Cambridge, Mass., gave a thorough discussion of the theory of nonlinear capacity converters.

M. C. Waltz and R. V. Pound at the MIT Radiation Laboratory observed negative IF conductance when units like North's were used. Pound gave many interesting details about measured power and gain and also measured negative IF conductance. He obtained a 10-db gain and reasoned that such a receiver should have a better noise figure than that of a conventional converter which has conversion loss. He was unable, however, to achieve this.

In 1948, A. van der Ziel and, in 1949, V. D. Landon also derived the MAVAR gain relationships; the former also pointed out the low-noise figure possibilities.

In 1952, C. F. Edwards observed nonreciprocal behavior in converters when he used R. S. Ohl's bombarded silicon diodes which exhibited variable capacitance as well as variable resistance characteristics. This observation again triggered a sequence reminiscent of the North diode sequence of the 1940's in which Apker, Smith, Pound, and Waltz reported the experimental results and Torrey, van der Ziel, and Landon derived the theory. Corresponding names for the early 1950 sequence are Ohl, Edwards, Manley, and Rowe.

However, in neither of these sequences was a very low-loss variable capacitance diode available and hence the gain was limited and the noise figure was not especially good.

In 1954, the United States Signal Corps sponsored a project at Bell Telephone Laboratories, Murray Hill, N. J., to develop semiconductor devices. In the second interim report of this now famous "Task 8," A. E. Bakanowski published his derivation of the nonlinear capacitor as a mixer. The work of Bakanowski, Cranna and Uhlir led to the discovery of a technique for making low-loss units.

The technique of making low-loss silicon diode varactors or varicaps advanced rapidly and interest in these new units began to expand.

In the meantime, H. Suhl discovered that variable reactance in the microwave range was obtained in ferrite materials when properly excited by a pumping frequency. He proposed using this effect to obtain parametric amplification and discussed suitable materials in the paper published in 1957. M. T. Weiss verified Suhl's proposal experimentally.

M. E. Hines and H. E. Elder succeeded in demonstrating gain and oscillations in a reactance amplifier which used silicon varactors and suggested several microwave circuits for up-converters and negative resistance amplifiers. Their work stimulated activity in microwave applications of "varactor" diodes.[2]

In 1957, Heffner and Wade considered theoretically the noise, gain and bandwidth of parametric amplifiers.

Early in 1958, the low-noise properties predicted by theory were verified experimentally at the Bell Telephone Laboratories at 6000 mc by Uenohara and at 380 mc by Engelbrecht. Salzberg at Airborne Instruments Laboratory, Mineola, N. Y., and Heffner and Kotzebue at Stanford University, Stanford, Calif., also achieved low-noise performance working at 1 mc and 1200 mc, respectively.

Miyakawa in Japan, Cullen in England and Tien and Suhl in America considered the amplification and frequency conversion in propagating circuits in which the variable reactors were distributed along a transmission line while Bloom, Chang and Wittke of RCA Laboratories, Princeton, N. J., took up the theory of parametric amplification and discussed the new approaches to amplification of microwaves. Bloom and Chang also discussed the case of low frequency pumping.

R. S. Engelbrecht at Bell Telephone Laboratories designed a traveling wave UHF parametric amplifier using varactor diodes and achieved over 200-mc bandwidth at UHF with 8 to 10 gain. Measurements indicated an "astronomy" noise figure of one db, corresponding to a "radar" noise figure of about 3.5 db. (This compares favorably with the best commercially available vacuum tube, whose noise figure is about 5 db.)

In the meantime, Adler of Zenith, Chicago, Ill. (in June, 1957), suggested a novel principle of signal amplification using a pumped electron beam, and Bridges (in February, 1958) suggested and constructed a parametric amplifier using the variable reactance of a floating drift tube klystron. Louisell and Quate discussed the capabilities of this type of amplifier, and Adler demonstrated that the conclusions concerning the low-noise capabilities were indeed correct. He achieved a noise figure capability of 1.4 db, of which 0.4 db represented the loss in the input coupler.

The development of the vacuum tube in Alexanderson's time curtailed the interest in radio frequency parametric transducers. Thirty or so years later, the invention of the transistor then diminished the interest in vacuum tubes. But the interest in radio frequency parametric transducers was resurrected by the development of the low-noise variable capacitance diode, and this resurrection, in turn, has stimulated the interest in vacuum tubes as parametric transducers.

What is the next cycle in this see-saw pattern?

Low-Noise Tunnel-Diode Down Converter Having Conversion Gain*

K. K. N. CHANG†, G. H. HEILMEIER†, STUDENT MEMBER, IRE, AND H. J. PRAGER†

Summary—**This paper describes the use of the new tunnel diode in a down converter. An experimental UHF circuit converting from a signal frequency of 210 mc to an intermediate frequency of 30 mc is used to illustrate the feasibility of this new converter. Conversion power gain of 22 db with less than 3 db noise has been achieved with gallium arsenide diodes. The circuit analysis proceeds from the basic nonlinear resistance of the tunnel diode I-V characteristic. Equations are developed for conversion gain, bandwidth and noise figure. From these equations, criteria are derived for the choice of diode characteristics and circuit parameters to obtain optimum performance.**

INTRODUCTION

THE low-noise, high-gain, conversion of a high-frequency signal to a lower-frequency signal has not been possible with previous mixer devices. Ordinary crystal mixers, which make use of the nonlinearity of their positive resistance, exhibit a conversion loss and a poor noise factor. The recently introduced parametric converters, which operate on a nonlinear capacitance or inductance basis, have achieved good noise factors with *up-conversion* gain. The parametric *down converters*, however, have poor noise factors. For such down converters, it is found that the excess noise factor (*i.e.*, the noise factor minus unity) varies roughly as the ratio of the input frequency to the output frequency. Thus, for a ten-to-one frequency down-conversion, the noise factor is around 10 db. Because of this frequency dependence, it is almost impossible to convert a microwave frequency into a low intermediate frequency with a reasonable noise factor by parametric converters.

The purpose of this paper is to report on a down converter using a tunnel diode (Esaki diode[1,2]) as the nonlinear resistance element. The fact that the negative resistance characteristic of a tunnel diode can be utilized to achieve low-noise amplification has already been demonstrated.[3] It is now shown that the nonlinearity of this negative resistance characteristic can be used for frequency conversion. Since the nonlinearity of a resistance, *not* a reactance, is utilized for frequency conversion, the noise factor is independent of the ratio of the input frequency to the output frequency. Thus, by using a tunnel diode, a low-noise down converter with conversion gain has been achieved.

ANALYSIS

The converter circuit to be analyzed is shown in Fig. 1, which also establishes the notation to be used in the following analysis. The three tank circuits which resonate at ω_1, the input signal frequency; ω_2, the difference frequency; and $\omega_3 = \omega_1 + \omega_2$, the local oscillator frequency, are coupled together by the tunnel diode.

The analysis proceeds in a manner entirely similar to that for the small signal nonlinear reactance case.[4] The I-V characteristic of the tunnel diode (Fig. 2) at the operating point P can be represented by a quadratic relation:

$$I = G_0 V - \mathcal{G} V^2. \tag{1}$$

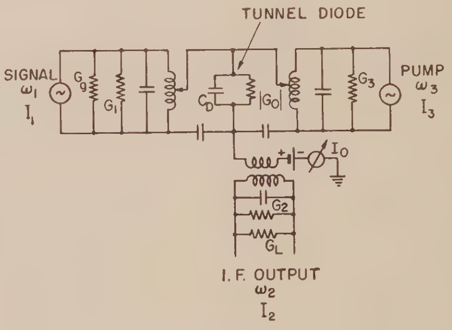

Fig. 1—Schematic diagram of converter circuit.

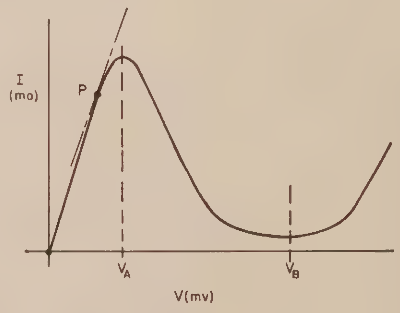

Fig. 2—Tunnel-diode I-V characteristic.

An operating point in the positive resistance region is chosen for reasons to be discussed later. The currents at the three frequencies are:

$$I_1 = V_1(\bar{G}_1 + j\bar{B}_1) - \mathcal{G} V_2^* V_3$$
$$I_2 = V_2(\bar{G}_2 + j\bar{B}_2) - \mathcal{G} V_1^* V_3$$
$$I_3 = V_3(\bar{G}_3) - \mathcal{G} V_1 V_2 \tag{2}$$

where

$$\overline{G}_1 = G_1 + G_g + G_0$$

$$\overline{G}_2 = G_2 + G_L + G_0$$

$$\overline{G}_3 = G_3 + G_0$$

$$\overline{B}_1 = \omega_1 C_1\left(\frac{\omega}{\omega_1} - \frac{\omega_1}{\omega}\right)$$

$$\overline{B}_2 = \omega_2 C_2\left(\frac{\omega_3 - \omega}{\omega_2} - \frac{\omega_2}{\omega_3 - \omega}\right). \tag{3}$$

The small signal analysis neglects the effect of the nonlinear interaction on the local oscillator current. Hence, $\mathcal{G}V_1V_2$ is neglected in the third equation of (2).

In (3), G_1, G_2 and G_3 are the loss conductances of the respective circuits. These loss conductances consist of the circuit and the tunnel diode ohmic losses. The capacitances, C_1 and C_2, similarly consist of the circuit and tunnel diode capacitance, C_D.

A. Conversion Power Gain

The conversion power ratio under matched conditions is defined as

$$g_c = \frac{V_2^2 G_L}{\dfrac{I_1^2}{4G_g}}. \tag{4}$$

Solving (2), one obtains

$$g_c = \frac{4\mathcal{G}^2V_3^2G_gG_L}{[\overline{G}_1\overline{G}_2 - \mathcal{G}^2V_3^2]^2}. \tag{5}$$

Eq. (5) is a general expression for the conversion power ratio. When G_0 is positive, the ratio can be either greater or less than unity, depending on the I-V characteristic of the nonlinear conductance. In order to obtain a conversion gain (*i.e.*, $\sqrt{g_c} > 1$) with a positive G_0, it follows from (5) that

$$\sqrt{g_c} = \frac{2\dfrac{\mathcal{G}V_3}{G_0}}{\dfrac{1}{\sqrt{G_gG_L}}\left\{\dfrac{(G_g+G_1)(G_L+G_2)}{G_0} + G_1 + G_2 + G_0\left(1 - \dfrac{\mathcal{G}^2V_3^2}{G_0^2}\right)\right\} + \sqrt{\dfrac{G_L}{G_g}} + \sqrt{\dfrac{G_g}{G_L}}} > 1. \tag{6}$$

Since

$$\sqrt{\frac{G_L}{G_g}} + \sqrt{\frac{G_g}{G_L}} > 2 \tag{7}$$

when G_0 is positive, (6) is satisfied if

$$\frac{\mathcal{G}V_3}{G_0} > 1. \tag{8}$$

Eq. (8) is the necessary condition for gain. This equation shows, together with (1), that the I-V characteristic whose origin is at the operating point (such as P in Fig. 2) must exhibit a maximum value, and that the local oscillator voltage V_3 must be sufficiently large so that it swings the current below the value of the current at the operating point. In the case of an ordinary crystal detector, the I-V characteristic exhibits no such maximum and (1) and (8) can never be satisfied simultaneously. It is important to note that (8) can be satisfied when the operating point is chosen in the region where $V < V_A$ and where G_0 is positive.

For the region $V > V_B$, (8) still applies. In this region, however, the diode current is due to minority carriers and so it is probably not suitable for high frequency conversion.

For the region $V_A < V < V_B$, the G_0 is negative and stable biasing becomes critical. It is difficult to find a stable operating point without having the device break into spurious oscillations, because of the large voltage swing of the local oscillator.

In order to normalize the conversion power ratio (5), let:

$$\lambda = \frac{\mathcal{G}^2V_3^2}{\overline{G}_1\overline{G}_2} \tag{9}$$

$$Q_g = \frac{\omega_1 C_1}{G_g} \tag{10}$$

$$Q_L = \frac{\omega_2 C_2}{G_L} \tag{11}$$

$$\overline{Q}_1 = \frac{\omega_1 C_1}{\overline{G}_1} \tag{12}$$

$$\overline{Q}_2 = \frac{\omega_2 C_2}{\overline{G}_2} \tag{13}$$

$$\bar{g}_c = \left(\frac{Q_g}{\overline{Q}_1}\,\frac{Q_L}{\overline{Q}_2}\right) g_c. \tag{14}$$

Eq. (5) then becomes

$$\boxed{\bar{g}_c = \frac{4\lambda}{(1-\lambda)^2}}. \tag{15}$$

B. Bandwidth

Assuming that the half-power frequencies are near the resonant frequency, the following approximation can be made:

$$\overline{B}_1 = \omega_1 C_1\left(\frac{\omega}{\omega_1} - \frac{\omega_1}{\omega}\right) \doteq 2(\omega - \omega_1)C_1 \tag{16}$$

$$\overline{B}_2 = \omega_2 C_2\left(\frac{\omega_3 - \omega}{\omega_2} - \frac{\omega_2}{\omega_3 - \omega}\right) \doteq 2(\omega_1 - \omega)C_2. \qquad (17)$$

By defining the relative bandwidth as $B_1 = \Delta f_1/f_1$ and defining

$$S_1 = 2\overline{Q}_1 B_1 \qquad (18)$$

and

$$c = \frac{\overline{Q}_2\omega_1}{\overline{Q}_1\omega_2}, \qquad (19)$$

one obtains

$$S_1{}^2 = \frac{[2c(1-\lambda) - (1+c)^2] + \sqrt{[2c(1-\lambda) - (1+c)^2]^2 + 4c^2(1-\lambda)^2}}{2c^2}. \qquad (20)$$

For the case of high gain, *i.e.*, $\lambda \doteq 1$, (20) becomes

$$S_1 \doteq \frac{1-\lambda}{1+c} \doteq \frac{1}{1+c}\,\frac{2[\sqrt{1+\bar{g}_c} - 1]}{\bar{g}_c} \qquad (21)$$

and the voltage gain-bandwidth product is

$$\boxed{\sqrt{\bar{g}_c}\, B_1 \doteq \frac{1}{1+c}\,\frac{1}{\overline{Q}_1}}. \qquad (22)$$

C. Noise Figure

The noise figure can be found by considering the currents in (2) to be due to the thermal noise sources of the circuits:

$$|\mathcal{I}_1|^2 = 4k\Delta f(G_g T_0 + G_1 T + G_e T)$$

$$|\mathcal{I}_2|^2 = 4k\Delta f(G_L T + G_2 T + G_e T) \qquad (23)$$

where

k = Boltzmann's constant,
T_0 = reference temperature (290°K),
T = ambient temperature,
G_e = equivalent shot noise conductance of the tunnel diode,
$G_e = eI_0/2kT$, I_0 = dc current of the tunnel diode, and
$|\mathcal{I}|$ = equivalent noise currents.

Eq. (2) can then be written as:

$$|\mathcal{I}_1|^2 = |V_1\overline{G}_1 - \mathcal{G}V_2{}^*V_3|^2$$

$$|\mathcal{I}_2|^2 = |V_2\overline{G}_2 - \mathcal{G}V_1{}^*V_3|^2$$

$$|I_3|^2 = |V_3\overline{G}_3 - \mathcal{G}V_1V_2|^2. \qquad (24)$$

From the definition for the noise figure, one obtains

$$F = \frac{P_{\text{in}}}{P_{\text{out}}}\,\frac{N_{\text{out}}}{N_{\text{in}}} = \frac{1}{g_c}\,N_{\text{out}}\,\frac{1}{kT_0\Delta f} = \frac{|V_2|^2 G_L}{g_c k T_0 \Delta f}. \qquad (25)$$

After solving (24) for $|V_2|^2$ and substituting, (25) becomes

$$\boxed{F = 1 + \frac{T}{T_0}\left[\frac{G_e}{G_g} + \frac{G_1}{G_g} + \frac{(G_L + G_2 + G_e)\overline{G}_1}{G_g\overline{G}_2}\,\frac{1}{1 - \dfrac{2(\sqrt{1+\bar{g}_c} - 1)}{\bar{g}_c}}\right]}. \qquad (26)$$

EXPERIMENTAL RESULTS

An experimental circuit based on Fig. 1 and using coaxial lines has been built. The operating frequencies were $f_1 = 210$ mc, $f_2 = 30$ mc, and $f_3 = 240$ mc. Representative results are shown in Table I, and compared with computed values.

Figs. 3 and 4 show typical curves of the I-V characteristic of the germanium and gallium arsenide tunnel diodes that were used in the experiments in Table I. The germanium diode had a peak current of 35 ma at 62 mv; its operating point was chosen at 18 ma and 29 mv yielding a positive $G_0 = 0.42$ mho. The gallium arsenide diode had a peak current of 23.6 ma at 100 mv; the operating point was at 20 ma and 60 mv with a positive $G_0 = 0.20$ mho.

To complete the calculations according to (15), (22), and (26), it is necessary to know the values of certain circuit parameters. For the case of the experimental circuit of Fig. 1, the following values were measured. The values of λ were chosen to give agreement with measured gain ratios.

Germanium Diodes: $\lambda = 0.43$ $c = 0.1$ $\overline{Q}_1 = 100$ $G_g = G_L = 4$ mhos $G_1 \doteq G_2 \doteq 0$ $G_e \doteq 20I_0 \doteq 0.36$ mho: $G_0 = 0.42$ mho.

Gallium Arsenide: $\lambda = 0.88$ $c = 0.1$ $\overline{Q}_1 = 100$ $G_g = G_L = 4$ mhos $G_1 \doteq G_2 \doteq 0$ $G_e = 0.40$ mho $G_0 = 0.21$ mhos.

TABLE I

Diode	Power Gain		Bandwidth		Noise Figure		Sensitivity
	Measured	Computed	Measured	Computed	Measured	Computed	Measured
Germanium	6.0 db	6.0 db	0.9 mc	0.6 mc	5.2 db	4.4 db	1.5 μv
Gallium arsenide*	22.7 db	22.7 db	0.15 mc	0.26 mc	2.8 db	3.8 db	0.25 μv

* The gallium-arsenide diode is an experimental sample developed by A. Wheeler of the Advanced Development Group of RCA Semiconductor Division, Somerville, N. J.

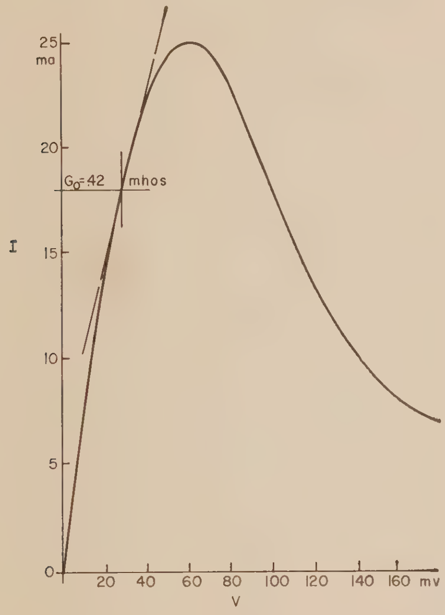

Fig. 3—Germanium tunnel diode.

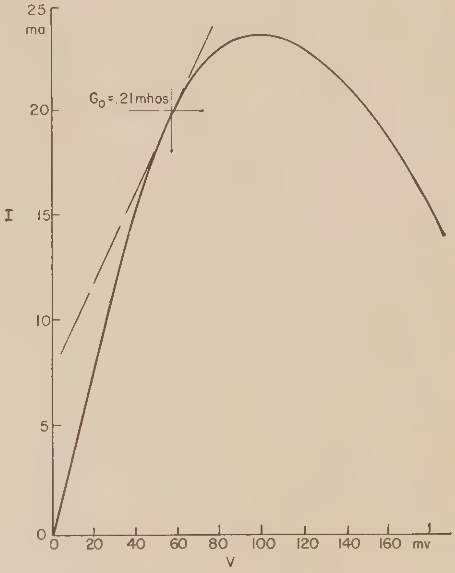

Fig. 4—Gallium arsenide tunnel diode.

Discussion

It is noted from Figs. 3 and 4 that the operating points for the diodes were chosen at a region where the slope of the I-V characteristic is positive. These operating points were established by the initial dc current from the bias supply and the rectified RF current of the local oscillator.

Conversion gain will result for positive G_0 when the requirements of (1) and (8) are met simultaneously (see Fig. 5). $\mathcal{G} V_3$ will be larger than G_0 when the RF voltage swing of the local oscillator is large enough to drive across the peak of the I-V curve and into the negative slope region until the instantaneous values of the current are smaller than the dc current at the operating point.

However, any appreciable voltage swing into the negative slope portion will make the system unstable, particularly when the negative slope is very steep. For this reason, it is more difficult to obtain high gain with germanium diodes, where the negative slope is much steeper, than for gallium arsenide. Had it not been for this stability problem, the germanium diodes would have yielded the same low-noise figure as the gallium arsenide diodes.

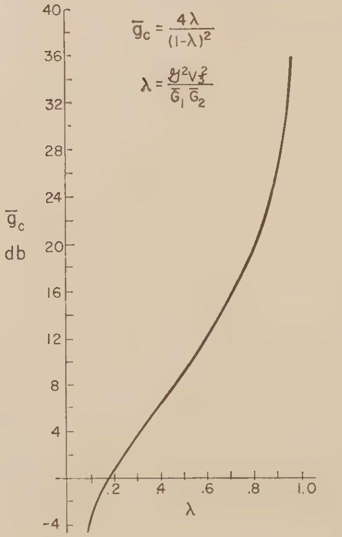

Fig. 5—"Normalized" conversion power ratio.

Further consideration of (22) and (26) will show the theoretical approach to optimum bandwidth and noise figure (Figs. 6 and 7). For improved bandwidth, the parameter c should be made small and the circuit's Q values should also be made small. Since $\bar{Q}_1 = \omega_1 C_1 / \bar{G}_1$, this immediately suggests that the circuit capacitances and

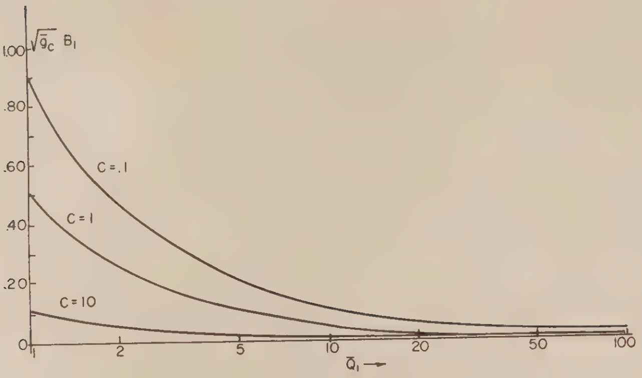

Fig. 6—Gain times bandwidth vs circuit Q for various

$$C = \frac{\bar{Q}_2}{\bar{Q}_1}\frac{\omega_1}{\omega_2}.$$

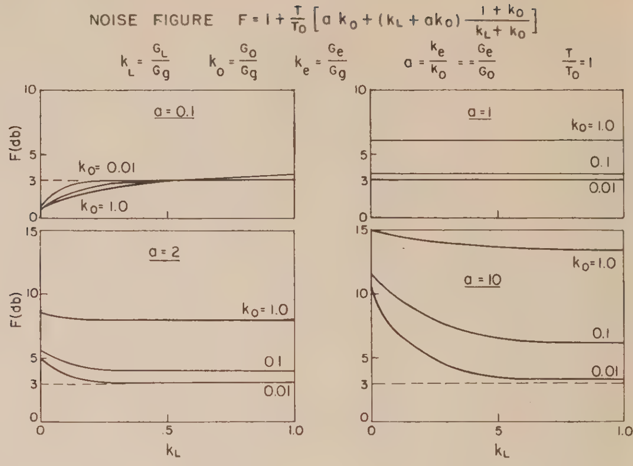

Fig. 7—Noise factor as a function of diode and circuit conductances.

especially the diode capacitance C_D should be made as small as possible. For a similar reason, G_g should be made larger than G_e to yield a low-noise figure.

The possibility of obtaining conversion using a lower pump frequency is to be noted. In this case, the nonlinearity of the diode characteristic could be used to produce the desired harmonic of the lower pump frequency for mixing. It is also noted that the possibility of making the diode-pump circuit self-oscillatory exists. Thus, direct down conversion can be obtained without a separate local oscillator.

Conclusions

The present experiments have demonstrated that the tunnel diode can be utilized as a *low-noise, high-gain down converter* in the UHF range. It seems feasible to extend the operating frequencies into the microwave region. The diodes for such applications should be designed with as low a capacitance as possible. The associated circuits, and especially the input circuit, should have high conductance and low Q's in order to realize optimum bandwidth and noise figures.

Noise Limitations to Resolving Power in Electronic Imaging*

J. W. COLTMAN† AND A. E. ANDERSON†

Summary—**A theoretical derivation, verified by experiment, shows that the maximum visible line number of a displayed bar pattern is directly proportional to the signal-to-white-noise ratio. The constant of proportionality and the effect of finite screen boundaries have been experimentally determined. It is found both theoretically and experimentally that the masking effect of white noise depends only on the noise power per unit bandwidth, and is independent of the upper frequency limit of the noise spectrum, provided that this exceeds the frequency limit set by the eye.**

These results can be used together with the aperture response of any imaging system to predict in quantitative terms the resolution limit as a function of the signal and noise levels. As an example, the theorems postulated are used together with the measured amplitude response function of the 5820-image orthicon to obtain a universal resolution vs signal-to-noise ratio curve for beam-noise-limited tubes of the image orthicon type. The predicted performance is in good agreement with experimental results. A similar set of curves for quantum-noise-limited image tubes is also given. The effects of object contrast variation, signal integration in time, and the presence of spurious background are presented.

I. Introduction

In recent years, there has been a widening interest in electronic imaging devices whose capabilities, with respect to sensitivity or spectral response, lie beyond that of the unaided eye. Television techniques, which permit arbitrarily high brightness amplification and contrast intensification, essentially remove most limitations of the human eye, so that performance is limited only by two system characteristics, the fidelity with which the image is reproduced, and the noise introduced into the information-bearing channel.

This paper deals quantitatively with the manner in

---

* Original manuscript received by the IRE, November 17, 1959.

† Westinghouse Res. Labs., Pittsburgh, Pa.

which system noise interferes with image resolution. In the first section, there are derived, from pure scaling arguments, some completely general relationships between visual image detectability and noise intensity. These relationships are then particularized to the case of television presentation, and some experimental data in verification of the theory are presented. In the second section, it is shown how deterioration of the signal for fine patterns, together with the previously established demands on signal-to-noise ratio, combine to set a quantitative limit on resolving power.

II. Noise Considerations

A. Signal-to-Noise Ratio Required for Detection of an Image

The ability of the eye to distinguish a pattern in a noisy signal has been previously investigated[1,2] for cases in which the noise was assumed to result from the quantum nature of the signal itself. The formulation is ordinarily in terms of pattern contrast and population of events (light or X-ray quanta) giving rise to the noise. In the case being treated here, and indeed in essentially all cases of television presentation, one deals with a different situation, where there is an additive noise independent of the signal strength, and the final image contrast, brightness, and magnification can be adjusted at will by the observer. This paper establishes image detection limits which are independent of these last named quantities. Limiting resolutions are expressed solely by the signal-to-noise ratio as measured at some critical point in the system.

It is possible to derive certain relationships between image detail and signal-to-noise ratio required without recourse to any experiment. The argument which follows is not restricted to television-type displays, but, subject to the postulates given, applies to any display whatever.

This thought experiment is best conducted by first postulating a viewing screen, infinite in extent, producing light at an average brightness B, which fluctuates in time and space. Let the nature of this fluctuation correspond to "white" noise, that is, the light flux L per steradian from any area A has an average value AB and is distributed in a Gaussian fashion with a standard deviation $\Delta L = m\sqrt{AB}$. (This kind of "noisy" illumination is typified, for example, by an area emitting light in the form of uniform flashes, randomly distributed in time and space.) No particular value of m need be assumed, *i.e.*, it is permissible to subtract a constant value B_0 from the average brightness or to change the gain of the system, provided that the occurrence (mathematically speaking) of a negative value of light flux is a very rare event in any area of practical interest.

A viewer stands before this screen, and an operator superimposes on the noisy background described above a signal image of specified form and size. The operator then slowly reduces the signal strength until the image is no longer visible to the observer. During this process, the observer is free to change his viewing distance, add or subtract a constant brightness B_0 (subject to the condition mentioned above) and change the "gain" of the system, which operates on both the signal and noise alike. These are the operations known as "contrast enhancement" in a television system. Eventually, a value of signal will be reached which no longer permits the image to be distinguished in the noise, in spite of optimum adjustments on the part of the viewer. This is the threshold signal for the particular image and noise chosen, which we call Condition I.

Now three changes are made. The operator makes the image larger by a factor g, while the signal strength is left constant. He also increases the strength of the noise $m\sqrt{AB}$ by a factor g, to $gm\sqrt{AB}$. The viewer meanwhile is asked to increase his viewing distance by the same factor, g, and to leave all other parameters fixed. This is Condition II.

It is evident that the signal image is unchanged as far as the viewer is concerned; the increased viewing distance exactly compensates for the increase in pattern size, while the average apparent brightnesses, being independent of viewing distance, are fixed. What about the apparent fluctuation? This is unchanged also. In Condition I, an area A on the screen is projected to some area A' on the observer's retina. Under Condition II, this same element A' encompasses an area g^2A on the screen, because of the increased viewing distance. The operator has also changed the strength of the noise by a factor g, so that the standard deviation in the light flux per steradian corresponding to the area A' is now $gm\sqrt{g^2AB} = g^2m\sqrt{AB}$. The solid angle subtended by the observer's pupil is, however, less by a factor g^2, so we find that the fluctuation in brightness for any area A' on the observer's retina is exactly as in Condition I.

Thus, the visual effect received by the observer in Condition II is identical in all respects to that of Condition I. Since Condition I was an optimum as far as viewing distance, gain, and background brightness were concerned, then Condition II must also be an optimum, and represents again a threshold. Referring back to the changes made by the operator at the screen, we infer: *The strength of white noise required to mask an image signal is directly proportional to the linear size of the image.*

Because it is assumed that the viewer can change at will the gain, background brightness, and viewing distance, it is apparent that only the signal-to-noise *ratio* is important in determining the threshold. We may thus restate the results: *The signal-to-white-noise ratio required for detection of an image is inversely proportional to the linear dimension of the image.*

A corollary of the above may also be inferred from the

---

[1] A. Rose, "Sensitivity of the human eye on an absolute scale," *J. Opt. Soc. Amer.*, vol. 38, pp. 196–208; February, 1948.

[2] J. W. Coltman, "Scintillation limitations to resolving power," *J. Opt. Soc. Amer.*, vol. 44, pp. 234–237; March, 1954.

same argument: *The optimum viewing distance for detection of an image in white noise is directly proportional to the image size.*

B. Signals and Noise in Television Displays

In deriving the theorems of Section II-A, noise was specified only by the constant m in the expression $m\sqrt{AB}$ and the image size by a linear dimension. In the television case, it is more convenient to measure the signal and noise in the electrical channel prior to conversion to a pattern, and to use for a standard of length the width of the frame of the picture. For convenience in the derivations which follow, it is assumed that the light produced on the kinescope face is directly proportional to the impressed signal. While this is not the case in practice, the threshold signals with which we deal are small, and since the "gamma" of the kinescope acts on signal and noise alike, the effect of the kinescope nonlinearity is equivalent, in the first order, to a simple change in system gain.

Assume a television image of a vertical sine wave bar pattern, having enough lines showing in the picture so that the effect of the finite frame size may be ignored. The theorem proposed states that the threshold signal-to-noise ratio is inversely proportional to the linear dimension of the image, or proportional to the number of lines N per cm.

$$N_{\text{threshold}} = \text{const}\left(\frac{\text{screen signal}}{\text{screen noise}}\right)\text{lines/cm.} \tag{1}$$

In (1) the screen noise is measured by the brightness fluctuation on some small area of the screen. It remains to relate this fluctuation to the noise impressed on the scanning beam.

Let the scanning beam current be i_0 and let it fluctuate with a noise of rms value i_n, measured over the bandwidth Δf. Consider an area A on the picture, small compared to the frame size but large enough to contain several resolution elements. In a time t larger than several frame times, there will be deposited in this area a total charge $q=(A/A_0)i_0t$, where A_0 is the frame area, or, more accurately, an extended frame area which takes account of the blanking and return times of the scans. This value of q will vary due to the fluctuation in i, but the fractional variation will be much smaller than that of i, because there are many samples of the beam current going to make up q. In measuring the noise current over a bandwidth Δf, we have effectively sampled the beam current by collecting charge over short times $1/2\Delta f$ in duration. In measuring q, however, the beam spends a time $(A/A_0)t$ in the area A, so that q contains $(A/A_0)2\Delta ft$ independent samples of the beam current. The fractional variation in q compared to that in the beam is reduced by the square root of this number. Thus

$$dq/q = (2\Delta ftA/A_0)^{-1/2}i_n/i_0. \tag{2}$$

The screen signal is related to q by a modulation factor which is the same as that for the beam current. Therefore

$$\frac{\text{screen signal}}{\text{screen noise}} = (2\Delta ftA/A_0)^{1/2}\left(\frac{\text{signal}}{\text{noise}}\right), \tag{3}$$

where both the signal and noise in the right-hand member are measured as currents or voltages in the electrical channel. It should be emphasized here that Δf is not necessarily the bandwidth of the system, but represents merely the frequency interval over which the noise was measured. It will be recognized that for white noise, the noise is directly proportional to $\sqrt{\Delta f}$, so that $\sqrt{\Delta f}$/noise is a constant independent of the bandwidth chosen, and is a measure of the spectrum level of the noise.

Combining (1) and (3),

$$N_{\text{lines/cm}} = \text{const}\,(2\Delta ftA/A_0)^{1/2}\left(\frac{\text{signal}}{\text{noise}}\right). \tag{4}$$

If the width of the displayed picture is W cm, the number of lines per picture is NW, and if A_0 is replaced by HW/e_ve_h, where H is the height and e_v and e_h are the sweep efficiencies, then (4) can be written as

$$N_{\text{lines/picture}} = k\left(\frac{Ate_he_v\Delta f}{R}\right)^{1/2}\frac{\text{signal}}{\text{noise}}, \tag{5}$$

where R is the aspect (height to width) ratio. Note that only this factor and the sweep efficiencies enter; the expression is independent of the number of scanning lines or the frame rate of the system.

It will be noted that in the derivation of (2) it was required that the minimum sample area A extend far enough to encompass several independent samples of i_n; *i.e.*, in terms of the television scan it must be several times wider than the resolution element set by the bandwidth. If the pattern detail is sufficiently large so that the eye can integrate over such an elemental area without decreasing the pattern contrast, then (5) can be expected to hold.

Now, if the noise in question arises, as is usually the case, from a white noise source located prior to the bandwidth-limiting circuits of the system, the noise current is itself proportional to $\sqrt{\Delta f}$. Eq. (5) in this case implies that *the threshold value for signal recognition is independent of the system bandwidth.*

The requirement on the sample area A noted above, and the use of an integrating time t larger than the frame time, is essentially equivalent to assuming that the eye, and not the system, sets the bandwidth. Since it is probable that the eye does not curtail the bandwidth sharply, pattern detectability may decrease somewhat as the bandwidth is gradually increased over the minimum required. Eventually, however, pattern detectability will become constant and independent of further increases in bandwidth.

The fact that the spectrum level of white noise required just to perceive the noise itself is independent of the noise bandwidth, is discussed by Mertz.[3] In that work, he finds a square "sampling area" for the eye of about 5 minutes of arc in linear dimension; this is consistent with the optimum viewing distance indicated in Fig. 3.

C. Experimental Determination of the Visibility Thresholds for a Bar Pattern

To test the relationships derived in the previous section, an experimental investigation of the visibility of sine wave bar patterns was carried out using a television monitor displaying accurately-measured sine wave signals and white noise. It should be noted that television kinescopes do not, in general, respond linearly (in light flux) to the voltage applied to the grid, so that we depart in this respect from the conditions postulated in the theory. For small signals and noise, this lack of linearity is of no consequence, as it merely introduces an extra gain in the system. For large signals, the noise will no longer be Gaussian. The extent of the departure from theory is left for experimental determination.

A block diagram of the equipment is shown in Fig. 1. The noise source was a temperature-limited thermionic diode, operating into a high-gain video amplifier. The amplifier characteristic was such as to give a noise power uniformly distributed within ±1 db from a few kilocycles to about 4.5 mc, with a rapid drop-off to a few per cent at 5.5 mc. The total curve could be approximated by a rectangular distribution extending to 5.0 mc. A coherent sine wave oscillator generated a sinusoidal bar pattern variable over the entire frequency band. An rms milliammeter with response flat to 8 mc was used to measure either the noise or the signal, which were then mixed and fed to the display kinescope. An attenuator was provided in the oscillator circuit to reduce the signal to any desired value. Brightness and contrast could be controlled on the monitor after the signals were measured and mixed.

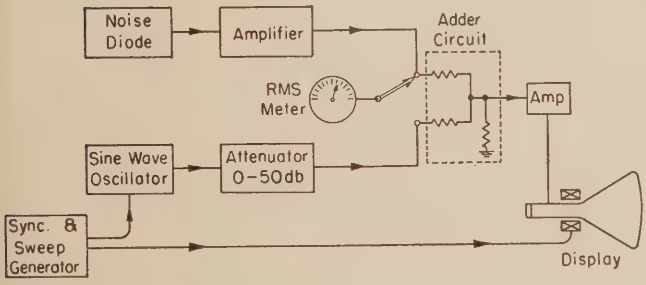

Fig. 1—Arrangement for displaying measured signals and noise. The synchronized sine wave oscillator produced a vertical sine wave bar pattern of variable intensity on the display, while a fixed measured white noise was superimposed.

The experimental procedure was to seat the subject before the television screen at a chosen distance, select a bar pattern of the desired number of lines (the number of line pairs per picture was taken as the number of cycles of the oscillator between blanking pulses, not all of which were visible on the screen because of masking) and set the noise and signal power equal by means of the noise meter. Correction was made for blanking periods, so the signal-to-noise ratios quoted represent those during the active period. The signal attenuator was then set to a value near the threshold of pattern visibility. The subject was asked whether or not he could discern the presence of the pattern, and after a "yes" or "no" response, the attenuator was reset to a neighboring value. At each condition, some 18 to 24 responses were requested, the attenuator being varied at random among three or four settings separated by 2 db. The setting (or interpolated setting value) at which the observer responded "yes" 50 per cent of the time was taken as the threshold of visibility. In almost all cases, a clean dividing line could be made, a typical situation being that in which six out of six responses were "yes" at 20 db, three out of six were "yes" at 22 db, and all were "no" at 24 db. Signal-to-noise ratios used in this paper are based on current rather than power, so that a 2-db step represents a 26 per cent change in signal current.

While an unequivocal result could usually be obtained in a single test, it was evident that an individual's threshold for a given set of conditions was not constant, but could vary by 50 per cent or more with time. Variations among individuals were also apparent. The amount of data taken was limited, and conditions of surround brightness, time interval between tests, etc., were not carefully controlled, so that the data presented here do not constitute a definitive study of this particular visual parameter. They suffice, however, to demonstrate the relationships derived above, to provide a numerical value of the constant k in (5), and to outline the area of validity of the theoretical treatment.

D. Experimental Results

Since the theory presupposes an optimum viewing angle for a given pattern, an attempt was made to establish this angle. With a fixed pattern, a single subject was tested at viewing distances ranging from $\frac{1}{4}$ to 7 meters. Several repeats at two meters were taken to check for uncontrolled shift of the threshold. Evidence of a considerable shift is given in Fig. 2, where threshold attenuator settings are plotted, not against distance, but against order number of the trials. The circled points are all for two meters. The points are labeled with the distance. In an attempt to extract some information, it was assumed that the threshold shift was gradual, and could be represented by the dotted line through the two-meter points. Deviations from this line by the other points were taken as representing a distance effect.

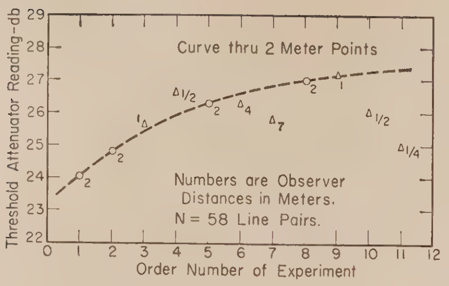

Fig. 2—Threshold readings taken at various distances as labeled on the points. Drift of the threshold is evident from the curve through the 2-meter points. All readings are with $N=58$.

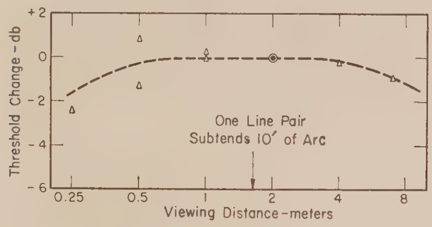

Fig. 3—Relative threshold as a function of viewing distance. Data are taken as the departure of points from the curve of Fig. 2. The extreme broadness of the optimum is evident.

The results are plotted in Fig. 3. There is some suggestion of an optimum near 1.5 meters, where one line pair subtends about 10 minutes of arc, but the most striking result is the broadness of the distribution. The effect of changing distance over a range of 30:1 is hardly outside the experimental error in determining the threshold. Thus, in succeeding tests, the subject assumed viewing distances roughly proportional to the pattern line width, but no attempt was made to control this factor rigidly.

The results of a series of runs using varying numbers of line pairs (cycles) per picture are given in Fig. 4. The solid line drawn with a 45-degree slope demonstrates the expected proportionality between line number and signal-to-noise ratio. It is of great interest to note the extremely small signal-to-noise ratios required, clearly showing the great extent to which integration takes place in the eye. From the position of this line and the 5.0-mc bandwidth used, we can evaluate the constant in (5) and write:

$$N_{\text{threshold}} = 615 \sqrt{\Delta f} \cdot (\text{signal/noise}), \qquad (6)$$

where Δf is measured in megacycles, and N is line pairs per picture width.

The earlier work on scintillation limited square wave bar patterns by Coltman[2] can be reformulated in terms of signal-to-noise ratio by calculating the noise power which the scintillations would generate in a circuit of bandwidth Δf, and taking account of blanking times and picture aspect ratio. When this is done, we arrive at the expression: $N = 640\sqrt{\Delta f} \cdot$ (signal/noise), which is in good agreement with (6). The constant in both cases is independent of the number of scanning lines and frame times, but will depend on the aspect (height to width) ratio and the fraction of the time spent in blanking, in the manner expressed by (5).

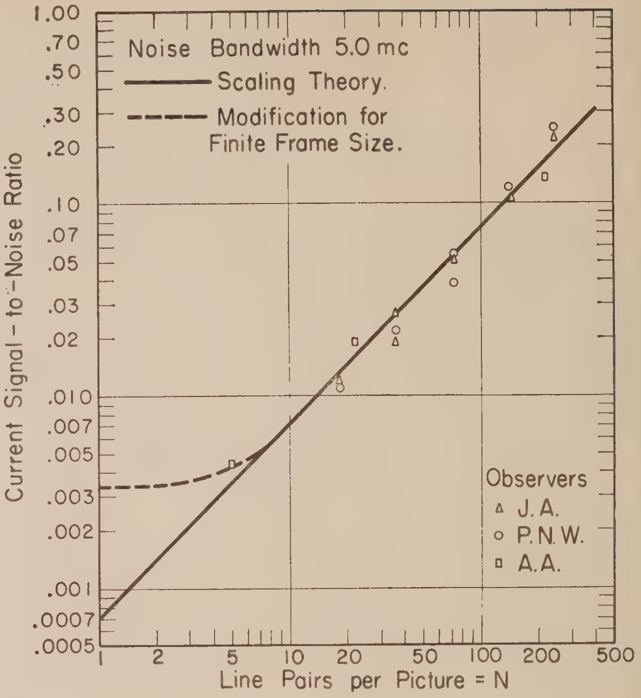

Fig. 4—Threshold signal-to-noise ratio as a function of number of cycles of the sine wave bar pattern displayed. The linear relationship extends over two decades, and departure is observed only for very small line numbers.

It is clear that while the scaling argument predicts a straight-line relationship over all values, the finite size of the screen will introduce departures for large line spacing. In order to determine the shape of the curve for very low numbers of line pairs per picture, a separate experiment was run. Here, the displayed picture was left fixed, and a series of cardboard aperture masks were employed to vary the number of lines seen by the observer.

The results, plotted in Fig. 5, show that the observer probably uses no more than seven line pairs in making an identification. As the number which he is permitted to see is decreased, the signal required rises rapidly, being greater by a factor of four when only one line pair is presented. The curve of Fig. 5 was used to draw the dotted lower portion of the curve of Fig. 4 by applying to the extension of the straight line the measured increase in signal required. A lower limit to the threshold signal-to-noise ratio for the largest complete sine wave pattern which can be shown is thus found to be about 1/300, where the noise is measured over 5 mc.

A fourth experiment was made to demonstrate the effect of bandwidth. A capacitor was arranged to be switched across the input circuit so as to reduce the bandwidth from 5 mc to about 600 kc. The total integrated noise power was thereby reduced by a factor of 7.6, and the rms noise current by a factor of 2.8. An 11-line pattern, whose frequency was so low as to be essentially unaffected by the bandwidth change, was dis-

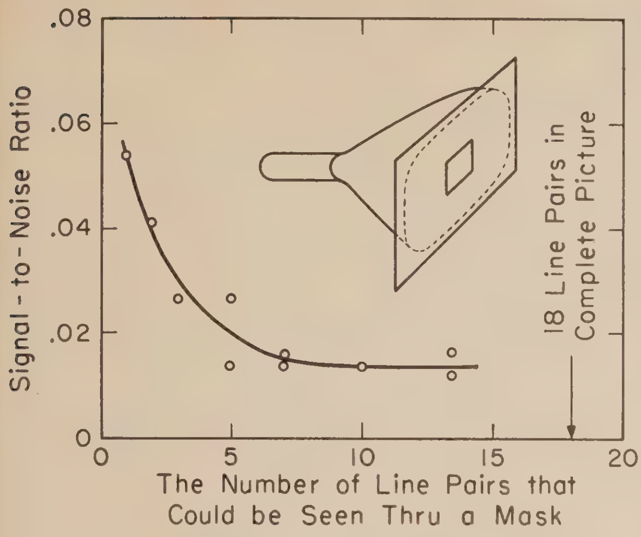

Fig. 5—Effect of frame limitation on signal-to-noise ratio required. These data were used to extend the curve of Fig. 4 to low line numbers.

played. Threshold measurements were taken while the capacitor was switched in and out at random intervals. It was found that the observer required 25 per cent less signal when the narrow bandwidth was used. While the shift was not zero, it was small compared to the large factor in noise current. This indicates that the over-all bandwidth was being set primarily by the eye, though it was still being affected somewhat by the system. A more carefully arranged experiment with sharp cutoff filters and optimum viewing distance for the observer would delineate more clearly the manner in which the eye can ignore high frequencies when looking for a low-frequency pattern.

III. ESTABLISHING THE RESOLUTION LIMIT

The theoretical and experimental information presented in Section II establishes the signal-to-noise ratio required to perceive a given line number. In many types of imaging systems, it is possible to determine by calculation what signal-to-noise ratio will be obtained, and this is also a function of line number. With these two pieces of information, one can determine quantitatively the resolution limit—the line number which can no longer be perceived by the eye—as a function of the input conditions and system parameters. A few cases which represent basic situations are discussed below.

A. Noise Independent of Signal

The signal current in the information channel will, of course, be a function of many system parameters. In particular, as a result of finite scanning apertures, electron-optical aberrations, etc., the signal response will diminish for fine patterns. It is convenient to describe this effect by the sine wave response function,[4] which

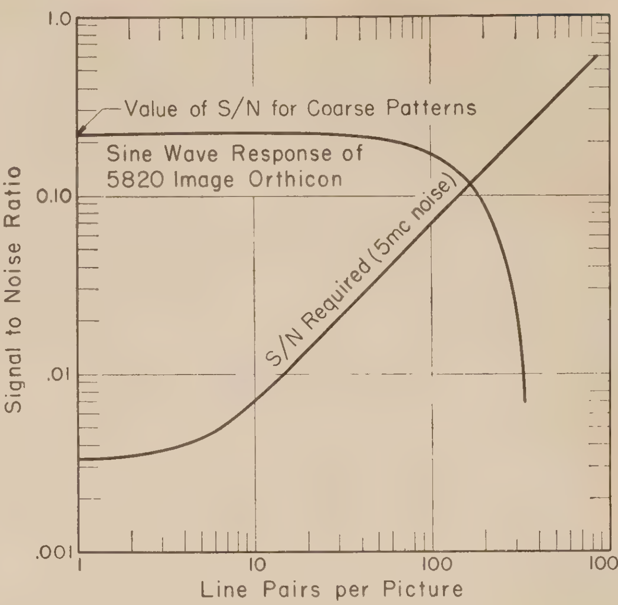

Fig. 6—Limiting resolution established by the intersection of curves representing available and required signal-to-noise ratio.

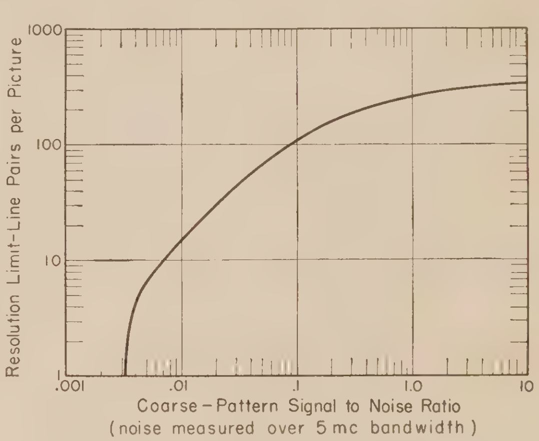

Fig. 7—Calculated resolution limit for a typical image orthicon as a function of the signal-to-noise ratio for large patterns.

gives the relative signal strength as a function of the space frequency of a sine wave test pattern. Such a response curve for a typical image orthicon is plotted as the upper curve in Fig. 6. The intercept at a signal-to-noise ratio of 0.22 is arbitrarily chosen for an example. The value is maintained essentially unchanged for low line numbers, and is called here the coarse-pattern signal-to-noise ratio. At higher line numbers the signal (and therefore the signal-to-noise ratio) diminishes as shown. Also plotted in Fig. 6 is the previously derived curve of Fig. 4 which establishes for each line number the threshold of signal-to-noise ratio. The abscissa of the intersection of the two curves gives the resolution limit corresponding to the coarse-pattern signal-to-noise ratio chosen.

By making a series of such choices, the curve of Fig. 7 is derived, which gives the resolution limit as a function of the coarse-pattern signal-to-noise ratio. The curve approximates over a decade a direct proportion between signal-to-noise ratio and resolution limit; it drops rapidly at the lower end due to the inability of the finite picture to display enough lines, while at the upper end it flattens out as the effects of finite focal spots reduce the available signal.

---

[4] J. W. Coltman, "The specification of imaging properties by response to a sine wave input," *J. Opt. Soc. Amer.*, vol. 44, pp. 468–471; June, 1954.

It should be noted that these curves assume an electrical channel of flat response and wide bandwidth. The 5-mc band over which the noise is measured is used only to establish a numerical value for the signal-to-noise ratio. Both noise (assumed white) and signal may extend well beyond this limit.

For an image orthicon operated at low light levels, the noise is essentially fixed, so that the signal-to-noise scale can be replaced by a properly established scale of scene illumination. The conversion factor will be a function of the photo-surface response, the optics used, and the object contrast, but the shape of the curve will remain fixed. Experimental confirmation is afforded by some data taken by Hannam[5] on two image orthicons employing different target materials, giving the observed resolution as a function of illumination. These data have been plotted in Fig. 8 with the illumination scale shifted for each tube to obtain the best fit to the theoretical curve. Considering the semi-subjective nature of such measurements, the agreement is satisfactory.

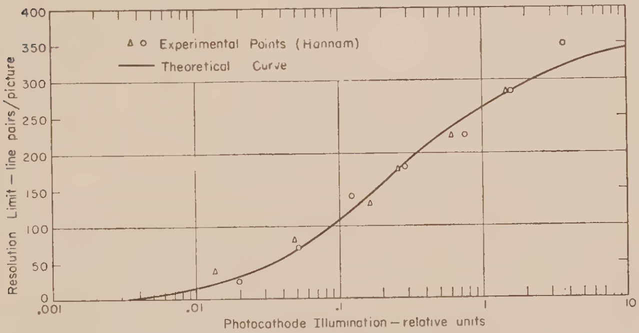

Fig. 8—Comparison of experimental and calculated resolution for two image orthicons.

B. Noise a Function of Signal

Optical imagining systems will finally be limited in detectivity by the quantum noise inherent in the light itself. The relationship between highlight illumination and resolution limit will no longer have the form of Fig. 7, since the noise is a function of the signal strength. The case of a signal pattern of 100 per cent contrast and a pickup system where no noise is introduced other than that associated with the quantum nature of the light represents the ultimate in detectivity. The coarse-pattern signal-to-noise ratio now becomes proportional to the square root of the signal itself. Rather than working in terms of a signal-to-noise ratio which remains to be measured on the particular equipment at hand, the results can be generalized by employing as an independent variable the number of quanta registered per unit time. This number will be directly proportional to the illumination on the scene, the constant of proportionality being determined by the effective size of the optical aperture and the dimensions and quantum efficiency of the receiving photosurface.

Let n be the number of photoelectrons ejected per second from the entire photosurface when it is uniformly illuminated at the level corresponding to the highlight scene brightness. If a sine wave pattern of 100 per cent contrast is then used as a test object, the peak-to-peak signal current during the scan is ne/e_he_v where e is the electronic charge and e_h and e_v the horizontal and vertical scan efficiencies. The corresponding rms signal current is $ne/\sqrt{8}e_he_v$. The average current $\bar{\imath}$, which is just half of the peak current, gives rise to an rms noise current equal to $\sqrt{2e\bar{\imath}\Delta f}$. The signal-to-noise ratio during the active portion of the scan is then:

$$\text{SNR} = \sqrt{n/8e_he_v\Delta f}. \tag{7}$$

In order to use the curves of Fig. 6 and Fig. 7, the values of $\Delta f = 5 \times 10^6$ and $e_he_v = 0.79$ corresponding to the test conditions are substituted, to yield

$$\text{SNR} = 1.80 \times 10^{-4}\sqrt{n}. \tag{8}$$

The validity of this procedure may be questioned for values of n such that less than one impulse is received in a half-cycle of the upper frequency of 5 mc. It is necessary again to point out that the 5-mc bandwidth assumed for the calculation of Figs. 6 and 7 is an arbitrary means of specifying the noise power per unit bandwidth of a white noise spectrum. Because the eye integrates in time and space, (7) is a valid transformation factor for relatively small values of n, even though it does not predict the result which would be obtained by measurement in the electrical channel with a wide-band noise meter. The correctness of this argument is borne out by the visual experiments by Coltman,[2] which show that the relationship (6) is followed for values of n at least as low as 1000 per second.

Using (8) and the curve of Fig. 7, it is possible to calculate the performance of a hypothetical imaging system whose optical fidelity is the same as that of the image orthicon, but which has no noise other than the inherent shot effect of the initial photoelectric surface. The relation between the resolution limit and the photoelectron emission rate for this case is shown as curve 1 of Fig. 9. It is extremely broad and extends to the remarkably low limit of about 400 flashes per second.

In practice, complete freedom from extraneous noise is an ideal rarely to be expected. For example, at room temperature, thermionic emission from the photoelectric surface will contribute a fixed electron emission rate which should be included in $\bar{\imath}$ in calculating the signal-to-noise ratio. If n_0 is the fixed emission rate which must be added to the rate $n/2$ due to the signal, we obtain as a modification of (8) the expression

$$\text{SNR} = 1.8 \times 10^{-4}\frac{n}{\sqrt{n + 2n_0}}. \tag{9}$$

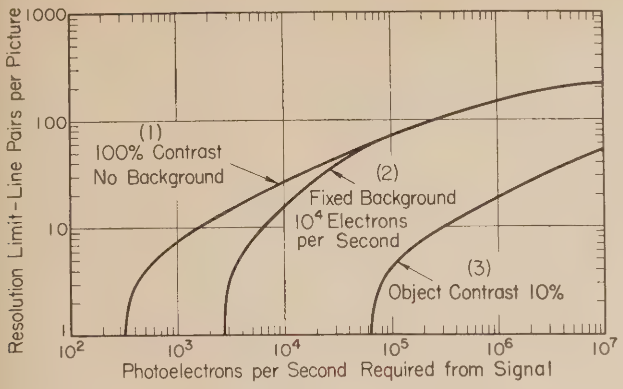

Fig. 9—Calculated resolution limits for cases where noise originates solely in the photocathode of an image orthicon type tube.

The effect of a fixed background emission of 10^4 electrons per second is illustrated by curve 2 of Fig. 9.

C. Effect of Contrast Reduction

While a 100 per cent contrast test pattern makes a convenient test object for specifying system performance, the scenes to be viewed in practice may often have relatively low contrast values. Contrast is defined here in terms of the highlight brightness, *i.e.*, for a sinusoidal test pattern, as follows:

$$C = (B_{\max} - B_{\min})/B_{\max}.$$

In the case where the noise is independent of the signal, loss of contrast simply means a corresponding loss of signal, so that the curve of Fig. 7 retains its shape while the scale of illumination is appropriately altered. Thus, in going from a 100 per cent to a 10 per cent contrast test pattern, the illumination must be increased by a factor of 10 to achieve the same resolution.

When the noise is due purely to the shot effect in the photosurface, a loss of contrast is attended by a similar loss of signal, but an increase of illumination to counteract this loss will also increase the noise. By a procedure similar to that used in the derivations of (7) and (9), a general expression is obtained which takes account both of fixed noise n_0 and contrast C, both referred to the maximum emission rate n due to the light alone, as follows:

$$\text{SNR} = 1.8 \times 10^{-4} \frac{nC}{\sqrt{n(2 - C) + 2n_0}} \cdot \qquad (10)$$

Curve 3 of Fig. 9 shows the relatively drastic effect of contrast reduction in the case of quantum noise only. A reduction of contrast from 100 per cent to 10 per cent now requires for compensation not ten times the illumination but 190 times. It will be appreciated, however, that the quantum noise is always present, and that the fixed noise case represents merely the situation where the additive noise is so large that it swamps out the quantum noise. When $n_0 \gg n$, (10) reduces to the case where the signal-to-noise ratio is directly proportional to the illumination and the contrast.

D. Effect of Integration in Time

The integration time of the eye is generally accepted to be approximately 0.2 second, a value which can be determined by comparing still photographs taken with various exposure times with impressions received of live pictures of noisy material. While this was not done quantitatively in the above work, some remarks on the expected effect of time integration may be appropriate. In a conventional television pickup system, light is collected for a time τ (1/30 second) before the information is scanned off and presented. If this time is lengthened to T the signal may be enhanced (in a properly operating storage medium) by a factor T/τ. If the noise arises solely in the subsequent system, it need not be presented to the eye during storage, and the visual signal-to-noise ratio is improved by a similar factor.

In the case of noise arising solely from the photoelectric shot noise, the situation is quite different. As long as the frame time is short compared to the integration time of the eye (0.2 second) the visual signal-to-noise ratio will be independent of the frame time or the duration of the individual flashes. Integration by storage means or by a long persistence phosphor will be effective only if it extends the integration time beyond that of the eye. The exact effect of added integration can be calculated only through a convolution of the decay characteristic of the eye with that of the storage system employed. However, a rule-of-thumb frequently employed in convolution processes indicates that the effective total integration time will approximate the square root of the sum of the squares of the two individual times. Thus the illumination required to achieve a given resolution will vary as

$$[(T/0.2)^2 + 1]^{-1/2},$$

where T is the system integration time in seconds. For values of T much less than 0.2 second, the illumination required is independent of T; for large values it is inversely proportional to T, so that the product of the illumination and the time, *i.e.*, the exposure, is constant.

CONCLUSIONS

For imaging systems whose output is viewed by the eye, and which are limited by white noise, the resolution limit can be predicted from a knowledge of two parameters, the noise power per unit bandwidth, and the sine wave response of the system. Because the demands on signal-to-noise ratio increase linearly with the line number, and the sine wave response usually falls off with at least the square of the line number, the resolution limit varies only slowly with signal input. The range of object illumination over which the resolution is appreciably varying may extend over several decades. In specifying the performance of systems designed to operate in the noise-limited region, it is thus highly desirable to give the entire resolution vs illumination curve, since neither the large-object detection limit nor the resolving power in the absence of noise (the two most frequently used characteristics) is a well-defined quantity.

Packaged Tunable L-Band Maser System*

F. R. ARAMS†, SENIOR MEMBER, IRE, AND S. OKWIT†, ASSOCIATE MEMBER, IRE

Summary—A low-noise tunable *L*-band maser system is described. The maser uses a pink ruby crystal oriented at 90° and is tunable from 850 to 2000 mc. The voltage-gain bandwidth product is as high as 37.5 mc at a liquid helium bath temperature of 1.5°K. An *L*-band circulator has been developed for use with the maser. It has an insertion loss of 0.3 db, operates over a 200-mc frequency range at *L*-band, and determines the usable tuning range of the circulator-maser system. The maser and circulator have been packaged into an operational unit that includes all auxiliary components, and has a system noise factor of 0.5 db (35°K). Electrical and mechanical features of the system are described and performance data are given.

I. Introduction

THE low-noise characteristic of the three-level solid-state maser amplifier has stimulated the interest of workers in a number of fields where the ultimate in receiver sensitivity is required. Radio astronomers, for example, are particularly interested in using a maser as a preamplifier for a 21-cm interstellar hydrogen-line receiver. Because of the Doppler shift in the frequency of the hydrogen line in receding galaxies, an *L*-band maser amplifier, which covers 1420 mc and tunes down in frequency, is of great practical interest. A packaged tunable maser system is described that tunes over a 200-mc frequency range at *L*-band.

Fixed-frequency *L*-band masers have been operated using chromium-doped potassium cobalticyanide.[1,2] Furthermore, gadolinium-doped hydrated lanthanum ethyl sulfate with cerium impurity[3] and chromium-doped aluminum oxide (ruby) had given satisfactory operation at higher microwave frequencies.[4–7] Ruby was chosen for our maser, because of its excellent physical, mechanical, and chemical characteristics, even though it had not previously to our knowledge been used as a material for *L*-band maser operation. Its characteristics include favorable "zero-field" splitting of the energy levels, good crystal line width, favorable relaxation times, low dielectric loss, machinability to accurate dimensions, resistance to cracking upon repeated temperature cycling, chemical inertness, and availability.

It was found[8] that *L*-band maser operation using ruby could be achieved, and satisfactory gain-bandwidth products obtained. In our design we placed emphasis on the feature of tunability. A tuning range from 850 to 2000 mc was obtained. Since a low-loss four-port *L*-band circulator was not available, such a unit, having a 200-mc frequency range for use with the maser, was developed.[9]

The maser and circulator were then packaged with the necessary auxiliary equipment to form a complete low-noise *L*-band preamplifier having a system noise factor of 0.5 db (35°K).

II. System Description

A schematic diagram of the maser system is shown in Fig. 1. The signal received by the antenna is directed by the four-port circulator into the single-port cavity maser; the amplified signal leaves the maser by the same

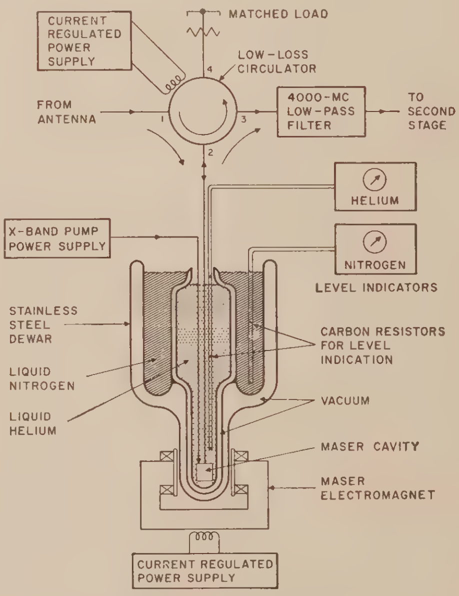

Fig. 1—Schematic diagram of maser system.

port and is directed by the circulator to the second stage. A low-pass filter having a cutoff frequency of 4000 mc is placed at the output of the maser system to prevent feed-through of pump power into the receiver. At this location, the filter will not adversely affect system noise factor.

A matched load is connected to the fourth port of the circulator. This load can be refrigerated if it is necessary to reduce its noise contribution caused by antenna mismatch (which reflects load noise into the maser).

The maser cavity (which is described more fully in Section III) is located near the bottom of a 2-inch inner diameter stainless-steel double Dewar flask. The inner portion of the Dewar flask is filled with $2\frac{1}{4}$ liters of liquid helium, which is allowed to enter the maser cavity. One charge of liquid helium yields approximately 16 hours of operation. The outer jacket of the Dewar flask is filled with liquid nitrogen to reduce liquid helium evaporation. The Dewar flask is constricted at the bottom to a $2\frac{1}{4}$-inch outer diameter to keep the dimensions of the maser electromagnet to a minimum. The maser electromagnet employs a 5-inch diameter pole-face and provides a magnetic field that is homogeneous within ±5 gauss out of 2000 gauss over the volume occupied by the ruby crystal.

Liquid level indicators are provided for the refrigerants. These use three carbon resistors connected in parallel and located at various heights in the Dewar flask. Liquid levels are displayed on two ammeters. A relay-actuated warning light indicates when a new charge of liquid helium is required.

The X-band pump power circuitry (shown in Fig. 2) consists of 1) a Varian X-13, 100-mw, klystron with a dial mounted on its tuning shaft that is directly calibrated in frequency, 2) an isolator that helps to stabilize the klystron by protecting it from load variations, 3) a variable attenuator that allows for pump power level adjustment, and 4) a 20-db bidirectional coupler to sample the pump output that is detected and displayed on a microammeter (this monitors the pump power level). The power reflected from the maser cavity is also sampled by the bidirectional coupler, detected, and fed to an oscilloscope to permit observation of the maser cavity resonance. For this purpose, the klystron is frequency-modulated using sawtooth modulation from the klystron power supply. A reaction frequency meter is included to permit accurate determination of pump frequency.

III. Tunable Maser Cavity Design

For maser operation, it is desirable that the cavity containing the paramagnetic material (ruby) be resonant at both the signal and pump frequencies. Furthermore, it is desirable that 1) these two cavity resonances be independently tunable, 2) the tuning be accomplished from the top of the Dewar flask while the cavity is in the liquid helium, and 3) the cavity coupling at the signal frequency be adjustable so that gain and bandwidth can be varied during operation.

The cavity design used, which meets all of these requirements, is shown in Fig. 3. This structure has the additional feature of simple mechanical design for making the required tuning and coupling adjustments.

The signal-frequency mode consists of a quarter-wavelength TEM-mode resonator.[1] This resonator is a thin-rod center conductor between parallel ground planes provided by the broad walls of a small X-band waveguide. This type of structure has the advantages that 1) resonant wavelength is proportional to rod length, 2) cavity coupling remains reasonably constant with frequency, and 3) the RF magnetic field distribution over the paramagnetic material remains essentially unchanged while the cavity is tuned. Because the TEM mode is dominant, the problem of spurious responses is minimized. A tuning range of more than one octave is obtained simply by varying the length of the center-conductor rod. The rod length is reduced by a factor of about three because of the high dielectric constant of the ruby. This is desirable at L-band to keep physical dimensions small. The unloaded Q of this structure is 550 at room temperature and increases to 1100 at 4.2°K.

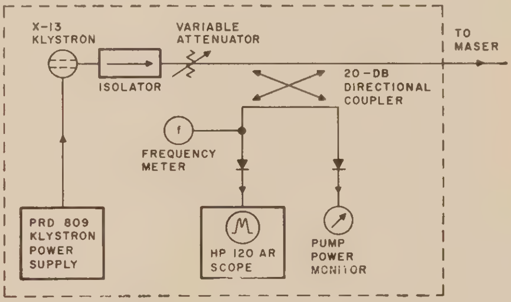

Fig. 2—Schematic diagram of X-band pump power supply.

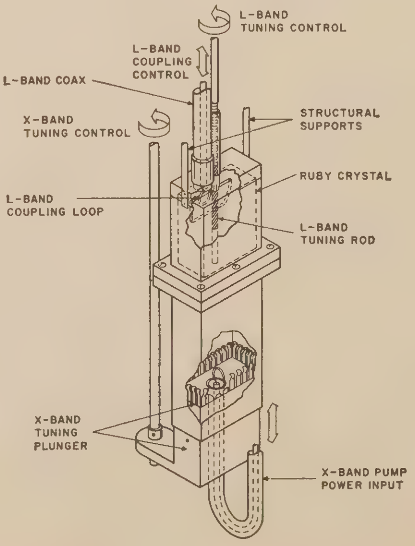

Fig. 3—Tunable maser cavity structure.

The waveguide region not occupied by the rod is beyond cutoff for the signal frequency. Therefore, a contacting plunger located in this region can serve as the tuning element for the X-band pump resonance (which operates in a TE_{107} mode) without affecting the L-band resonance (Fig. 3). The X-band pump power is loop-coupled into the cavity, through the backplate of the X-band tuning plunger, by means of a coaxial line having a bead-supported center conductor. Such a line has an X-band dissipative loss of only a few tenths of a db, has a much smaller cross section compared with waveguide, and the coupling remains reasonably constant over a broad tuning range. The X-band cavity is conveniently tuned from the top by a tuning rod directly connected to the tuning plunger. All low-temperature moving joints (except where electrical contact is required) consist of metal-to-teflon bushings.

Two factors were considered in choosing the 0.086-inch diameter of the L-band tuning rod: 1) the diameter should be as small as possible to minimize its effect on the X-band resonant frequency, and 2) the diameter dimension should yield a high unloaded Q at the L-band signal frequency. Measurements showed that the X-band resonance goes through a cyclical variation of only ±3 mc when the L-band resonance is tuned. The X-band tuning plunger is, as previously stated, in a region beyond cutoff for the L-band mode. Thus, the two resonances are independently tunable.

The coupling to the L-band mode is accomplished by means of a loop that penetrates into a thin slot in the ruby. The loop is oriented in a plane parallel to the broad waveguide dimension to minimize coupling to the X-band pump resonance. The coupling is variable from the top of the Dewar flask by means of a micrometer head that moves the L-band coaxial line in the vertical direction. This varies the penetration of the coupling loop into the maser cavity. Two other micrometer heads located at the top of the Dewar flask are used to tune the L- and X-band cavity resonances. The cavity assembly and the superstructure are shown in Figs. 4 and 5, respectively.

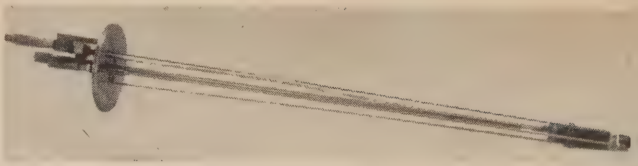

Fig. 4—Maser cavity assembly.

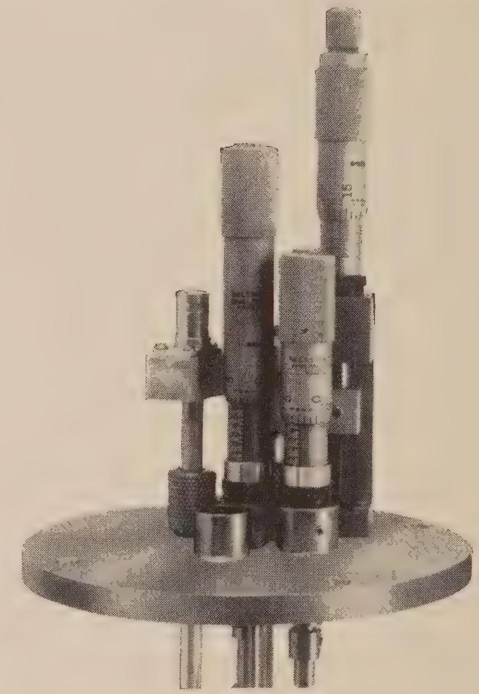

Fig. 5—Cavity superstructure.

IV. MASER PERFORMANCE

The relationship between the pump and signal resonant frequencies of the cavity and the external magnetic field required for maser operation are determined by the inherent quantum-mechanical properties of the paramagnetic crystal. These quantum-mechanical properties (energy levels, RF transition probabilities, and relaxation times) are strongly dependent upon the external magnetic field H and the angular orientation θ between the external magnetic field and the crystal C-axis.

Best L-band maser performance was obtained for an angular orientation θ of 90° at high magnetic fields ($H \approx 2000$ gauss). The energy level diagram for ruby when θ is equal to 90° is shown in Fig. 6. It shows four (low-lying) energy levels, since Cr^{+++} in Al_2O_3 has a spin $S=3/2$. The L-band signal transition and X-band pump transition that were used are between levels 1 and 2, and levels 1 and 3, respectively. The high-field 90° operating point is attractive on theoretical grounds because the calculated signal and pump transition probabilities are high.[10,11] At this operating point, the signal transition probability is maximum when the microwave signal magnetic field is nearly perpendicular to the external magnetic field and parallel to the ruby C-axis. This condition is realized to a fair degree in our design, since the ruby crystal that we utilized had its C-axis oriented in a plane parallel to the broad face of the X-band waveguide, and at 60° to the L-band tuning rod (see Fig. 3), and the signal magnetic field is elliptically shaped for slabline TEM mode employed.

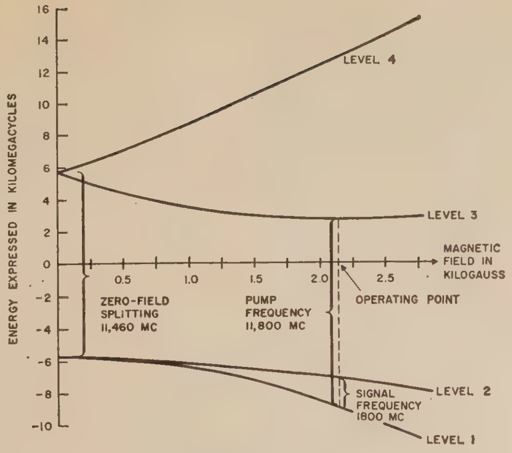

Fig. 6—Energy levels utilized for *L*-band maser.

Measurements of the voltage-gain bandwidth product at high magnetic fields were made at liquid helium bath temperatures of 4.2°K and 1.5°K. The results of these measurements are listed in Table I.

Table I shows that a voltage-gain bandwidth product of 37.5 mc was measured at 1750 mc for a temperature of 1.5°K. Thus, for a half-power bandwidth of 3.75 mc, a gain of 20 db will be obtained. Furthermore, operation was also obtained at an operating temperature of 4.2°K, where a voltage-gain bandwidth product as high as 20 mc was measured.

The gain-bandwidth products measured were used to calculate the effective magnetic Q. For such calculations, Fig. 7 and (3) (Appendix I) can be used, under the condition that the cavity unloaded Q is much greater than the external Q. The effective magnetic Q calculated at 1200 mc (Table I) is 140 and 210 for operation at 1.5°K and 4.2°K, respectively. The magnetic Q is approximately constant over the *L*-band region. There is a deterioration in magnetic Q at the low-frequency end that is probably due to cross-relaxation effects.[12] The pump power that was required varied between 5 and 150 mw for the various measurements.

A four-level experiment was also performed for θ equal to 90° at high magnetic fields. Here, pumping was done between levels 1 and 4, with the signal transition again between levels 1 and 2. Maser operation at a liquid helium bath temperature of 4.2° K was readily obtained at frequencies from 850 to 1750 mc (Table II). However, the measured voltage-gain bandwidth product did not show the expected improvement of greater than 100 per cent (assuming equal relaxation times between all levels) over the three-level arrangement. This may have been due in part to the limited pumping power available from the 20-kmc klystron that was used. Of the 50 mw available from a Raytheon QK306 klystron, only an estimated 10 mw reached the maser cavity. This power level was insufficient to saturate the 20-kmc pump transition, which has a low calculated transition probability.[10]

TABLE I

Summary of *L*-Band Maser Performance (Three-Level Operation)

Liquid Helium Bath Temperature (°K)	Signal Frequency (mc)	Voltage-Gain Bandwidth Product Measured (mc)	Voltage-Gain Bandwidth Product Determined from External Q Measurement (mc)	Pump Frequency (mc)	Magnetic Field (gauss)
4.2	2000	*	*	12,150	2260
4.2	1815	20	22	11,860	2150

[12] N. Bloembergen, S. Shapiro, P. S. Pershan, and J. O. Artman, "Cross-relaxation in spin systems," *Phys. Rev.*, vol. 114, pp. 445–459; April 15, 1959.

For convenient reference, we have plotted the energy levels in ruby in a manner that is particularly suitable for three-level tunable maser operation [Fig. 8(a) and 8(b)]. By plotting pump frequency as a function of magnetic field, with angular orientation θ and signal frequency as parameters, the variation in pump frequency and magnetic field for a given signal tuning range are readily determined. The region of operation used in our maser is indicated by a heavy line in Fig. 8(b).

This form of plotting the energy levels brings out an interesting and useful point, namely, that the ruby crystal can be readily oriented to 90° by varying the crystal orientation until the dc magnetic field required for resonance absorption is maximized. As Fig. 8(b) shows, this alignment technique can be applied to either the pump or signal transition.

V. Low-Loss Circulator

This is a four-port circulator having an insertion loss near 0.3 db and isolations greater than 23 db over a 200-mc frequency range.[9] Fig. 9 shows the circulator. Electrically, it consists of dual 90° non-reciprocal phase-shift sections connected to two hybrids.[13] Our unit used strip-transmission-line hybrids with transitions to a MgMnAl-ferrite-loaded *L*-band waveguide, which was reduced in height to one inch to keep the electromagnet dimensions at a minimum and to reduce the ferrite material requirements.

The strip-transmission-line hybrids are shown in detail in Fig. 10, with the top ground plane removed. The ring hybrid is equivalent in its operation to the waveguide folded tee, and the other hybrid is equivalent to the waveguide short-slot hybrid. The use of the strip-transmission-line hybrids results in reasonable physical size.

VI. Package Description and Performance

A. Description of Package

The over-all maser system is housed in two standard relay cabinets (Fig. 11). The smaller cabinet contains the maser cavity structure, stainless-steel Dewar flask, and maser magnet. The larger cabinet contains the associated auxiliary equipment, including (from top to bottom in Fig. 11):

1) oscilloscope to view either the pump or signal frequency cavity resonance and to observe and optimize maser action;
2) current-regulated power supplies to drive circulator and maser electromagnets;

5) liquid level indicators for the refrigerants.

The circulator (which cannot be seen in Fig. 11) is located in the rear of the larger cabinet and is connected to the maser by a low-loss strip transmission line having $1\frac{1}{2}$-inch ground-plane spacing. The input to the maser system consists of $1\frac{5}{8}$-inch coaxial line.

B. General Performance

The maser is easily tuned to any operating frequency over the 200-mc range by adjusting the dc magnetic field, the pump frequency, and the two cavity resonances. All the adjustments necessary for tuning the maser to a specific operating frequency have been calibrated. The signal-frequency cavity-resonance adjustment can be set to any specified frequency within ±2 mc with the calibrated micrometer head. One of the required adjustments, the dc magnetic field, is critical and requires fine tuning. The other two adjustments (pump cavity resonance and pump frequency) are not critical; maser operation can be obtained with the pump cavity resonance and pump frequency detuned as much as 75 mc.

The angular orientation θ of the ruby-loaded maser cavity with respect to the dc magnetic field is not critical. Maser operation has been obtained, without serious degradation in gain-bandwidth product, at angular deviations of several degrees from 90° throughout the tuning range. Consequently, controls for fine-tuning the alignment of the maser cavity were deemed unnecessary. A mechanical feature ensures that the maser cavity structure is correctly oriented when it is inserted into the system.

C. System Noise Temperature

Noise-temperature measurements were made on the maser system using the technique described in Appendix I. The noise generators used for the measurement consisted of two matched loads—one at room temperature and one at liquid nitrogen temperature (Appendix II). A series of measurements, made with the maser operating at high gains, yielded a noise factor of 0.5±0.1 db, which is equivalent to a noise temperature of 35°K.

The main contributing noise sources are:

1) The dissipative losses of the circulator and input coaxial feed lines; these give a noise temperature of approximately 28°K (0.4 db).
2) The second-stage amplifier and other components at the output of the maser having an over-all noise factor of 7.2 db (1230°K). The amplifier consists of a balanced mixer utilizing 1N21EMR crystals and a 30-mc IF amplifier. Its measured noise factor was 6.6 db. With a net maser system gain of 23 db, this contribution is 6.15°K.
3) The maser signal frequency spin temperature, which is calculated to be 1.5°K, for a bath temperature of 4.2°K, assuming equal idler and signal spin-lattice relaxation times.

Thus, good correlation is obtained between the calculated and measured noise temperatures.

D. Maser Saturation Characteristics

A saturation curve that was measured on the maser system is shown in Fig. 13. As can be seen, the gain drops 3 db at a power output of −35 dbm. This yields a dynamic range of 68 db for a post-receiver bandwidth of 1 mc.

Susceptibility of the maser to nearby CW signals is shown in Fig. 14. The power level of the interfering signal, at which the maser gain drops 3 db at its center frequency, is plotted as a function of the frequency of the interfering signal. The shape of the measured response can be closely determined from the frequency response of the active maser cavity. The measurement was made with a three-cavity filter between the maser and the second-stage receiver to ensure that the interference effect measured was primarily due to the maser proper. The filter had a 3-db bandwidth of 15 mc and an insertion loss of 25 db at 15 mc from center frequency.

It is essential that the input level of interfering signals be kept below the microwatt range (Figs. 13 and 14). To insure this, it is desirable to use a preselector cavity and/or passive ferrite limiter that has its limiting

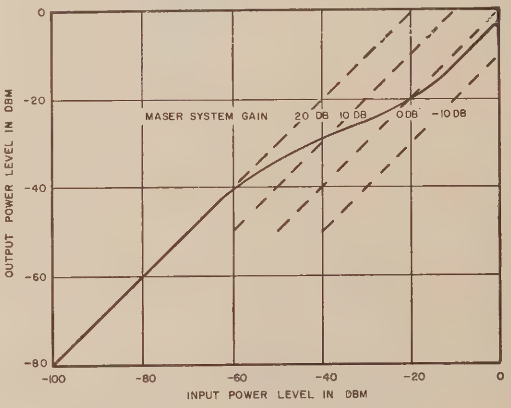

Fig. 13—Maser saturation characteristic due to main signal.

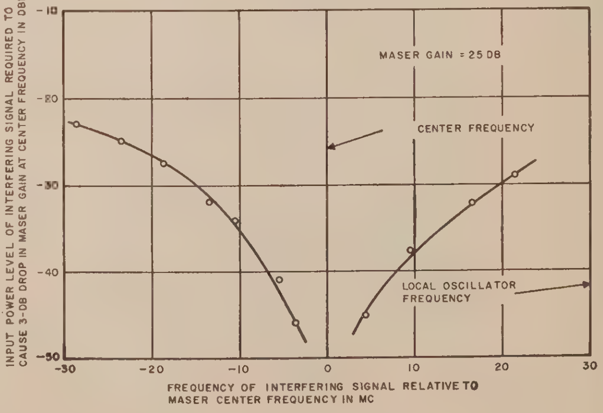

Fig. 14—Maser saturation characteristic due to nearby signals.

threshold at microwatt power levels.[14] These can be placed in the low temperature bath to minimize their noise contribution. The relatively low saturation power level (and relatively long recovery time) of the ruby maser is a result of the relatively long spin-lattice relaxation time of the idler transition, which (for θ equal to 90°) is in the tens of milliseconds at 4.2°K. Future masers will show marked improvements in saturation level and recovery time by using new materials or "impurity-doped" ruby to reduce the idler relaxation time.

To prevent maser saturation effects due to the local oscillator in the second-stage receiver, a balanced mixer should be used. A balanced mixer provides a local-oscillator isolation of 30 db, which, in combination with the circulator isolation and maser cavity selectivity, is more than sufficient to prevent maser saturation effects due to local-oscillator power leakage.

E. Gain Stability

The results of a number of stability measurements at a helium bath temperature of 4.2°K and a maser gain of 22 db yielded a long-term peak-to-peak drift of ± 0.55 db, and a short-term peak-to-peak stability of ± 0.1 to ± 0.2 db over a period of several hours. These figures represent the fluctuations of a complete receiver with the maser front end fed by a standard signal generator. Hence, a portion of the output variation must be ascribed to parts of the measurement setup rather than the maser.

Turbulence in the liquid helium appears to be responsible for some of the short-term gain variations observed in the maser. This effect is reduced by the use of polyfoam loading of the microwave structure. The fluctuations are also significantly reduced by reducing the helium bath temperature below the λ-point (2.2°K), where the liquid helium becomes a superfluid.

The parameter having the greatest detrimental effect on long-term gain stability was found to be the maser magnetic field, which is controlled by a current-regulated power supply. This is evident when it is noted that the regulation must be substantially better than the magnetic line width of the ruby, which is about 1 per cent of the external magnetic field that was used. The electromagnet is designed to permit maser operation over the entire 850 to 2000 mc tuning range of the cavity. Improved stability can be obtained by using a permanent magnet employing an adjustable mechanical shunt or bucking coils for tuning, since a variation in magnetic field of about 6 per cent is needed to cover the 200 mc tuning range of the maser system.

VII. Conclusion

It can be concluded that a cavity maser can be satisfactorily operated over frequency bands greater than one octave. In packaging such a maser together with a circulator for field operational use, the usual 12-inch diameter laboratory magnet and other highly precise supplementary equipment have been eliminated without detrimental effect on gain-bandwidth product, noise figure, and other system parameters. The resulting equipment is reasonably compact and easily operated by semi-skilled personnel.

Appendix I

Techniques for Measuring Maser Gain-Bandwidth Product

The voltage-gain-bandwidth product was determined by two methods. In the first method, gain and half-power bandwidth were measured directly, using the setup shown in Fig. 15. Maser gain is measured by noting the increase in generator output required to maintain a constant output meter reading when the maser is disconnected from the circuit and replaced by a short-circuit at point A of Fig. 15.

In the second method, the external Q of the maser cavity was measured with the pump power and magnetic field turned off. The voltage-gain bandwidth product $G^{1/2}B$ can then be calculated since, for the condition of high gain ($G^{1/2} \gg 1$), it is approximately

$$G^{1/2}B \approx \frac{2f}{Q_e}, \tag{1}$$

where f is the signal frequency and Q_e is the external Q. The more exact expression[15] for $Q_u \gg Q_e$ is

$$G^{1/2}B = \frac{2f}{Q_e}\left[\frac{G^{1/2}}{G^{1/2}+1}\right]. \tag{2}$$

The bracketed term in (2) is the correction factor on the approximation. It is plotted in Fig. 7, and is seen to be less than 10 per cent for gains greater than 20 db.

For comparison with theoretical computations of maser performance, it is desirable to determine Q_m, the magnetic Q, which is a measure of the negative resistance introduced by the paramagnetic maser material.

The magnetic Q is related to Q_e by the expression

$$\frac{Q_e}{Q_m} = \frac{G^{1/2} - 1}{G^{1/2} + 1}, \tag{3}$$

and is plotted in Fig. 7. Obviously, $Q_e \approx Q_m$ for high gains. The correction factor is less than 20 per cent for gains greater than 20 db.

Appendix II

Measurement of System Noise Temperature

Of the several methods used for the measurement of noise temperature,[16] the Y-factor method appeared to be most satisfactory for low noise temperatures. In this method, the output noise power of the receiver, when the input source resistance is at a high temperature T_2, is compared with the output noise power of the receiver when the input source resistance is at a lower temperature T_1. The ratio of these two noise powers is called the Y-factor, which is related to the noise temperature, T_e, by the expression

$$T_e = \frac{T_2 - T_1}{Y - 1} - T_1. \tag{4}$$

The accuracy with which T_e can be determined depends upon how accurately T_1, T_2, and Y are known.

Fig. 16 shows the experimental arrangement used for the noise measurement. The available noise power from the two loads (one maintained at a liquid nitrogen temperature of 77.3°K, and the other at room temperature) is alternately coupled to port 1 of the circulator through a coaxial switch. These noise powers are directed by the circulator into the maser (port 2) and from the maser into a second-stage amplifier consisting of a mixer and an AIL Type 130 Test Receiver. The Y-factor is then accurately determined by using a precision calibrated attenuator that is part of the AIL Type 130 Test Receiver.

It is estimated that the absolute temperature of the two loads can be determined to within ±1°K and that the Y-factor can be measured to within ±0.5 per cent.

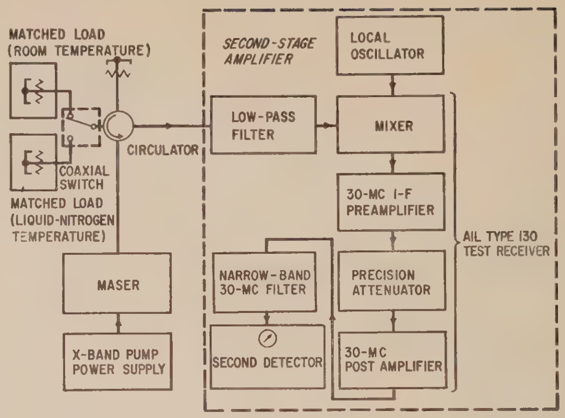

Fig. 16—Measurement setup for maser system noise temperature.

Application of these errors to a variational form of (4) yields a calculated over-all measurement accuracy of better than ±3°K.

In measuring low noise temperatures, the following precautions were taken.

1) The two noise generators (ambient temperature load and the liquid nitrogen load) were well matched.
2) Linearity measurements of the second-stage amplifier were made over a 40-db range. The linearity was found to be within ±0.05 db. In addition, the bandwidth of the second stage was made narrower than that of the first stage, to eliminate bandwidth corrections from the noise-factor measurement.
3) The over-all receiving system was tested for spurious responses. Since broad-band noise sources were used, all spurious responses must be known to reduce the measurement data accurately. All spurious responses were found to be negligible.

Acknowledgment

The advice and aid of C. H. Townes and A. Penzias of Columbia University during the early phases of the project are gratefully acknowledged. The authors also wish to express their gratitude to their co-workers, J. G. Smith and M. Grace, who helped with the packaging and with the measurements.

Cadmium Sulfide Field Effect Phototransistor*

R. R. BOCKEMUEHL†

Summary—**The experimental evaluation of cadmium sulfide field effect transistors indicates that, although the material does not compete with germanium for general transistor application, useful power gain was achieved and certain advantages exist for CdS in phototransistor applications. Many unique circuit functions can be performed by the device. The active electronic properties vary greatly with the intensity and wavelength of incident light, and with photoconductivity quenching infrared radiation. Voltage gains greater than 500, mutual transconductances up to 20 μmho and input resistances near 100 megohms have been observed. Electron-hole pairs are generated photoelectrically in the highly pure, single crystal CdS. The holes are virtually immobile and form a space charge when an applied electric field removes the mobile electrons from a region. Modulation of the space charge boundary by application of a potential to one terminal of the device produces modulation of the conductance between two other terminals and signal amplification results. Attempts to correlate the illumination sensitivity of the terminal characteristics with theoretical field effect parameters indicates the carrier distribution in the crystal is complex and varies with illumination wavelength and quenching intensity.**

INTRODUCTION

THE group II–VI compound semiconductors have potential advantages as specialized electronic components with transistor configurations. For example, the utility of photoconductive materials may be extended when fabricated as a transistor. Furthermore, transistor configurations facilitate observation of additional material properties and mechanisms which may extend theoretical understanding of semiconductors. The group II–VI compounds are not expected to compete with elemental or group III–V compounds as general-purpose transistor materials, inasmuch as those studied possess a prohibitively low carrier mobility, or low band gap, or high "intrinsic" carrier concentration.[1] The study of group II–VI transistors is important, however, on the basis of improvement of understanding and utilization of specialized properties, particularly photoelectric properties.

Cadmium sulfide was selected for transistor experimentation because its properties are probably the best known of the II–VI compounds and because it is available in sufficiently pure, single-crystal form.[2] The relatively low mobility of CdS (≈ 200) requires an excessively thin base layer in a junction transistor configuration. However, the unipolar field effect transistor configuration permits practical device dimensions even though mobility is relatively low.

The field effect transistor was first given detailed consideration by Shockley.[3] Modulation of the conductance of a unipolar semiconductor slab is achieved by applying an electric field, perpendicular to the current flow, creating a space charge region which effectively reduces the conducting cross section of the slab. In practice, the transverse field is applied through an intimate, but non-carrier-injecting contact such as a *p-n* junction. Application of the transverse field through an insulating medium does not produce an appreciable space charge in the semiconductor slab because of trapped charges which develop on the slab surface.[3]

Experimental field effect transistors have been fabricated from Ge[4] and Si,[5] and the effect has been observed in InP and GaAs.[6] However, no previous observation of field effect amplification has been reported for any group II–VI compound, nor for any material in which virtually all of the carriers are generated photoelectrically.

FABRICATION

The experimental field effect phototransistors were cut from thin single-crystal plates with a special air-abrasive cutting machine to dimensions of 3 mm × 3 mm square. Thickness was not modified and ranged from 0.15 to 0.5 mm in various units. The thin CdS crystal plates were grown by the vaporization-crystallization method by Boyd and Sihvonen.[2] The placement of the contacts is illustrated in Fig. 1. The contact nomenclature is consistent with that proposed by Shockley.[3] The gate contact is vacuum deposited copper, a few hundredths of a micron thick. The necessary rectifying characteristic is obtained by heating at 400°C for ten minutes in room air. The gate contact is transparent and back resistance is greater than 10^7 ohms. The formation of the rectifying junction is similar to that described by Reynolds, *et al.*;[7] however, the presence of air was found to be necessary during the heating process.

The ohmic source and drain contacts were prepared by electroplating indium from an indium fluoroborate solution after the gate contact heat treatment. All surfaces were cleaned and etched in HCl before contact application. Leads were connected to contacts with silver conducting paint. The units were mounted first on special printed circuit boards, and later in standard transistor headers with transparent cover as shown in Fig. 2.

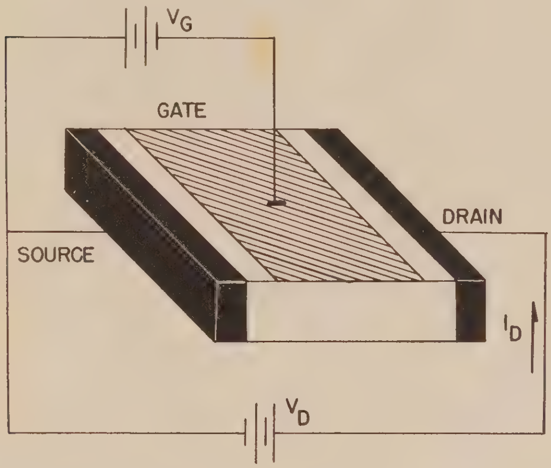

Fig. 1—Field effect phototransistor terminal relationship and common source connection. Source and drain are ohmic; gate is diodic and semitransparent.

Fig. 2—Cadmium sulfide field effect phototransistors. (a) Mounted for detailed evaluation. (b) Mounted in transparent transistor header.

Terminal Characteristics

The penetration of the space charge layer into the semiconductor slab, and the resulting decrease in the slab conductance is determined by the magnitude of the reverse bias voltage across the gate junction. Considering the grounded source terminal configuration, Fig. 1, the gate bias voltage is the difference between the potential applied to the gate terminal and the potential in the semiconductor slab. The latter is a function of the drain terminal potential. Thus, the slab conductance is a function of both gate and drain potentials.

The drain terminal voltage-current characteristic at various values of gate voltage (common source) is shown in Fig. 3. A "constant" current region of operation exists when the gate-to-drain potential difference is sufficient to cause the thickness of the space charge layer to approach that of the slab. This bias voltage is designated "pinch-off" voltage V_p. An increase in drain voltage above the V_p value alters the space charge distribution in such a manner to keep the pinch-off current essentially constant. The gate potential determines the value of the pinch-off current; thus an active gate-to-drain mutual transconductance G_m exists. The mutual transconductance, together with the high dynamic output impedance of the device, permits a large voltage gain to be realized. Furthermore, the high gate terminal impedance of the device permits useful current and power gains to be realized.

The terminal characteristics of the field effect phototransistor are dependent on the carrier density within the slab, which is determined by the intensity and wavelength of the incident light excitation. Therefore, these characteristics vary greatly with illumination parameters.

Typical characteristics of a unit when illuminated with an incandescent lamp at an intensity of the order of 200 foot-candles are as follows:

Pinch-off current ($V_g=0$): 200 μa,
Pinch-off voltage: 30 volts,
Mutual transconductance: 20 μmho,
Short circuit current gain: 400,
Open circuit voltage gain: up to 1000,
Output impedance (resistive): up to 50 meghoms,
Input impedance: 20 to 100 megohms depending on load resistance.

A finite gate-to-drain resistance exists which produces feedback resulting in the dependence of input impedance on load resistance and of output impedance on source resistance.

Several experimental phototransistors were operated in a temperature range from −50°F to 150°F with a negligible change in terminal characteristics when illuminated with an incandescent lamp. However, a considerable temperature dependence was observed when illuminated with monochromatic wavelengths greater than 5300 angstroms.

Frequency response varies greatly with operating conditions but extends from dc throughout the audio range.

High-frequency attenuation results from the junction capacity of the gate and from stray capacities in the drain circuit in conjunction with the high dynamic drain impedance.

Photoelectric Characteristics

The pinch-off current of the cadmium sulfide field effect phototransistor is much more sensitive to illumination intensity and wavelength than are the other electrical parameters of the device. The photoconductivity of cadmium sulfide exhibits a sharp peak between 5100 and 5200 Å.[8] The wavelength dependence of pinch-off current of the transistor, and the photocurrent when connected as a two-terminal photoconductor is shown in Fig. 4. Under certain operating conditions, the pinch-off current has been observed to be proportional to the square of the illumination intensity. Sensitivities of the order of 10^{-8} amperes per foot-candle squared have been observed with incandescent illumination.

The pinch-off current is also very sensitive to infrared quenching wavelengths.[9] Certain discrete wavelengths in the 1-micron region, when applied in combination with excitation wavelengths, cause a reduction in the conductivity of cadmium sulfide and produce other effects which sharply reduce the pinch-off current. This wavelength dependence of the pinch-off current and two-terminal photocurrent is shown in Fig. 5. Pinch-off current sensitivities of the order of 1 $\mu a/\mu w/cm^2$ have been observed. The variation of pinch-off current and two-terminal photocurrent with infrared quenching intensity is shown in Fig. 6. The pinch-off current is many times more sensitive to infrared quenching intensity than is the two-terminal photocurrent.

FIELD EFFECT PARAMETERS

Field effect theory in a photoconductor differs in detail from that in a doped semiconductor, although generalizations common to both cases can be derived. The parameters used in deriving theoretical relationships are common to both cases but some which are constant in doped semiconductors are variables when photoconductors are considered.

The electrical characteristics of a field effect transistor are dependent on the physical dimensions and the bulk properties of the semiconductor slab. The important dependent and independent parameters are summarized:

V_p = pinch-off potential, volts,
I_p = pinch-off current, amperes,
a = thickness, cm,
c = width, cm,
L = length, cm,
ρ = charge density, coulombs/cm^3,
k = dielectric constant, farads/cm,
μ = carrier mobility, cm^2/volt-second.

The following relationships are based on the gradual approximation defined by Shockley.[3] The potential within the semiconductor slab $V(y)$, the field E_y and the charge density $\rho(y)$ are related by Poisson's equation:

$$-d^2V(y)/dy^2 = dE_y/dy = \rho(y)/k, \tag{1}$$

where (y) is the distance from the gate surface. The induced charge is contained in the space charge layer and an increase in junction bias voltage increases the total space charge by extending the boundary of the space charge layer. The relationship between bias voltage and space charge layer thickness is dependent on the manner in which the space charge is distributed in the material. However, considering a general charge density distribution, the pinch-off potential can be derived from (1) in the following form:

$$V_p = (\rho_0 a^2/2k)[D_v], \tag{2}$$

where $[D_v]$ is a function of the charge distribution, and ρ_0 is the charge density at $y=0$.

Inasmuch as a potential gradient exists in the direction of current flow (x), the potential in the conducting channel and the resulting space charge boundary are both functions of (x), the distance from the source contact. Therefore the current density in the conducting channel is a function of (x). Furthermore, if free carrier distribution in the conducting channel is a function of (y), the conductivity $\sigma(y)$ and the current density J will be a function of (y):

$$J(x, y) = E_x\sigma(y). \tag{3}$$

Integration of (3) over suitable limits yields pinch-off current,

$$I_p = (a^3c\mu\rho_0^2/6kL)[D_1], \tag{4}$$

when the gate-to-source voltage equals zero.

The bulk conductance of the semiconductor slab with no space charge layer is

$$G_0 = (c/L)\int_0^a \sigma(y)dy = (\rho_0 acu/L)[D_g], \tag{5}$$

where $[D_g]$ is another function of carrier distribution.

The mutual transconductance G_m of a field effect transistor with zero bias between gate and source terminals is theoretically equal to the bulk conductance G_0 of the slab.

The portions of (2), (4), (5) which are in parentheses are independent of the charge distribution. The bracketed portions are dependent on charge distribution and are always dimensionless. The distribution functions will generally include the thickness parameter (a). The distribution functions for an exponential charge distribution are derived in the Appendix.

FIELD EFFECT IN A PHOTOCONDUCTOR

The principal differences encountered in consideration of field effects in a photoconductor and in a doped semiconductor result from the differences in the mechanisms which determine the space charge distribution and the carrier distribution in the material. In the analyses made by Shockley[3] and by Warner, *et al.*,[10] semiconductor materials such as Ge and Si were sufficiently activated with donors or acceptors to permit minority carriers to be neglected. The application of an electric field which removes the majority carriers from a region creates a space charge in that region with polarity opposite to that of the removed carriers. The distribution of the charge density in the space charge region is equal to the difference between donor and acceptor density in that region. Furthermore, the distribution of the carrier density in the conducting channel is equal to that of this activation density in the channel.

In an insulating photoconductor, however, electron-hole pairs are generated photoelectrically. In CdS and other n-type photoconductors, free holes produced by pair excitation are captured quickly by imperfection centers.[11] The resulting free hole mobility and lifetime have extremely low values; the holes can be assumed to be immobile in a first-order approximation. Application of an electric field to illuminated CdS, which removes the free electrons from a region, creates a positive space charge in that region in the form of trapped holes.

---

[10] R. M. Warner, W. H. Jackson, E. I. Doucette, and H. A. Stone, "A semiconductor current limiter," PROC. IRE, vol. 47, pp. 44–56; January, 1959.

[11] R. H. Bube, "Photoconductivity of the sulfide, selenide, and telluride of zinc or cadmium," PROC. IRE, vol. 12, pp. 1836–1850; December, 1955.

Inasmuch as the space charge and carrier distribution in a doped semiconductor correspond directly to the activation distribution, these values can be evaluated and applied to field effect equations. Furthermore, the distribution functions do not have first-order dependence on external parameters. In a photoconductor, however, the space charge and carrier distribution is an interdependent function of illumination intensity and wavelength, crystal inhomogeneities and electric field. The distribution functions are not only difficult to predict but also vary greatly with external parameters.

The carrier density in a photoconductor is equal to the rate at which the free carriers are generated per unit volume (excitation density) times the mean carrier lifetime in the conduction band before recombining with a hole. The carrier density distribution within the photoconductor slab is dependent on the distribution of the excitation density and on the manner in which the carriers may diffuse or drift from their generation sites. The excitation density at a particular point is proportional to the rate at which light is absorbed at that point. The light intensity distribution is a function of the incident light intensity J_0 and the absorption coefficient α and is related by Lambert's law:

$$J(y) = J_0 \exp(-\alpha y), \tag{6}$$

where (y) is the distance from the illuminated surface. The excitation density $f(y)$ is proportional to the rate of absorption:

$$f(y) = -dJ(y)dy = J_0\alpha \exp(-\alpha y). \tag{7}$$

The absorption coefficient α is a function of wavelength[8] and may vary over a range from 10 to 10^4 cm^{-1}. Thus illumination wavelength is important in determining the excitation density distribution.

Because of their very short lifetime as a carrier and low mobility, the generated holes do not drift an appreciable distance from their point of generation. The drift may not be entirely negligible at illumination wavelengths which yield a very high absorption coefficient, inasmuch as all of the carriers may be generated in an extremely narrow region near the surface. In addition, exciton diffusion lengths in CdS have been reported to be of the order of one cm and exciton production has been found to exceed pair production at certain wavelengths.[8] Excitons may diffuse into unilluminated regions of the crystal and dissociate into electron-hole pairs, thereby influencing charge distribution.

Carrier lifetime is probably nonuniform throughout the crystal, especially in the presence of infrared quenching radiation. Near-infrared radiation in the 0.89- and 1.35-micron regions cause a reduction of the photoconductivity of CdS, as shown in Fig. 5, by effectively reducing the carrier lifetime. A mechanism has been proposed whereby the infrared shifts the population density of certain recombination centers with a resulting increase in recombination rate.[9] The quenching effect is a function of the ratio of quenching intensity to excitation intensity.[9] Most excitation radiation is absorbed in relatively short distances in the crystal, while the absorption of the infrared quenching radiation is very slight. Thus, the ratio of quenching to excitation wavelengths increases with distance (y) from the illuminated surface, and the free carrier lifetime may be expected to decrease with (y), with a corresponding decrease in free electron and trapped hole density. The influence of quenching radiation on the charge distribution may be great and would account for the significantly greater effect of infrared on the pinch-off current than on the two-terminal photocurrent as shown in Figs. 5 and 6. The two-terminal photocurrent is proportional to the bulk conductance of the semiconductor slab. The bulk conductance (5) is proportional to the area under the charge distribution curve, independent of its shape, while the pinch-off voltage and current are extremely sensitive to the distribution characteristic.

All of the factors discussed so far affect the charge distribution in a perfectly homogeneous semiconductor slab. Additional factors exist in a practical device. For example, the carrier lifetime, mobility and infrared effects may be significantly different at the crystal surface than in the interior of the slab, effecting a charge distribution discontinuity near the surface. Furthermore, inasmuch as the gate is formed by heating a copper contact, the copper is diffused a small but finite distance into the crystal. The excitation density, carrier lifetime, mobility, infrared effects and the resulting charge distribution will be different in this "doped" region than in the bulk of the slab.

EXPERIMENTAL CORRELATION

Qualitative correlation of the experimental results with theoretical relationships is possible if an assumption of the charge distribution is made. Quantitative correlation is not possible because of incomplete knowledge relating the many factors which influence the charge distribution. Because of the exponential decrease of light intensity within the crystal, a simple first assumption is that the charge distribution decreases exponentially with distance from the illuminated surface. Then, if the gate surface is illuminated,

$$\rho(y) = \rho_0 \exp(-my), \tag{8}$$

where m is a factor which represents the combined effects of all the mechanisms producing the exponential reduction. With this distribution, the distribution functions in (2), (4), (5) are, as derived in the Appendix,

$$[D_v]_G = (2/m^2a^2)(e^{-ma} + mae^{-ma} - 1), \tag{9}$$

$$[D_I]_G = (3/2m^3a^3)[(2ma + 3)e^{-2ma} - 4e^{-ma} + 1], \tag{10}$$

$$[D_g] = (1/ma)(1 - e^{-ma}). \tag{11}$$

If the surface opposite the gate junction is illuminated, the charge distribution is reversed:

$$\rho(y) = \rho_0 \exp m(y - a), \tag{12}$$

$$[D_v]_0 = (2/m^2a^2)(ma + e^{-ma} - 1), \tag{13}$$

$$[D_I]_0 = (3/2m^3a^3)[(2ma - 3) + 4e^{-ma} - e^{-2ma}]. \tag{14}$$

Inasmuch as the bulk conductance is proportional to the area under the $\rho(y)$ curve, $[D_g]$ is not dependent on which surface is illuminated.

The ratio of the pinch-off current with opposite surface illuminated to that with the gate surface illuminated is equal to the ratio of the corresponding distribution functions:

$$(I_p)_0/(I_p)_G = [D_I]_0/[D_I]_G. \tag{15}$$

Pinch-off current ratios were obtained experimentally at several illumination wavelengths and quenching intensities. When the illumination was changed from the gate side to the opposite side, the illumination intensity was adjusted to yield a common value of bulk conductance. This partially compensates for the reduction of intensity by the semitransparent copper gate. Pinch-off current ratios in the range from 1 to 4 were observed, indicating a variation in the value of (ma) from 0 to 3.1. Thus, a qualitative variation of the charge distribution with both illumination wavelength and quenching intensity is indicated.

The measured value of pinch-off current ratio is subject to error inasmuch as the semitransparent gate reduces the effective incident illumination on only that portion of the surface beneath the gate. When illuminated from the gate side, the relative intensity is greater on the end portions than beneath the gate. However, when illuminated from the opposite side, the incident intensity is uniform over the entire surface. Inasmuch as the portions of the slab outside of the gate region act as degenerative feedback resistances,[4] the resulting feedback ratio will also change with direction of illumination. For this reason, the measured values of the pinch-off current ratios will be slightly lower than the ratios of their distribution functions.

The distribution functions $[D_I]_G$ and $[D_g]$ from (10) and (12), are plotted as a function of (ma) in Fig. 7. The experimentally obtained relationship between pinch-off current and two-terminal photocurrent as a function of infrared quenching intensity, Fig. 6, is qualitatively similar to the theoretical curves, Fig. 7. The similarity between the experimental and theoretical curves indicates that the assumed exponential distribution may not differ greatly from the actual distribution and that the exponent (m) increases with infrared quenching intensity.

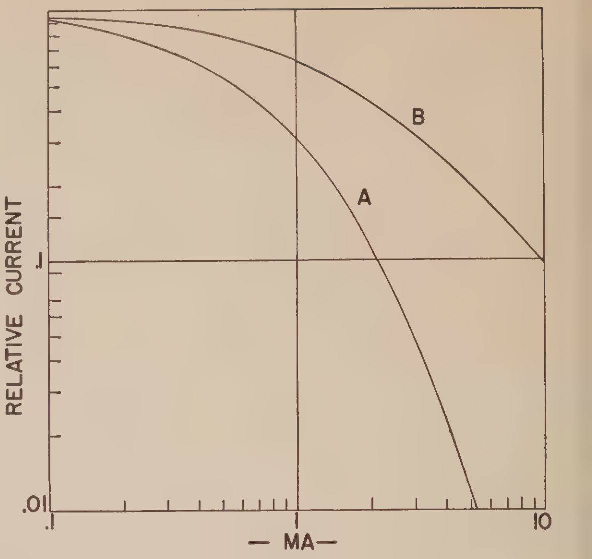

Fig. 7—Theoretical relationship between distribution function and the exponent (ma) with exponential charge distribution, for A) pinch-off current with gate side illuminated, B) two-terminal photocurrent.

Practical Applications

The unique characteristics of field effect phototransistors allow them to perform new and combined circuit functions which are not practicable with conventional circuit elements. Furthermore, they are solid state devices having the small size, high efficiency and ruggedness common to semiconductor components.

Direct connection of the gate-to-drain terminals yields a two-terminal current limiter similar to that described by Warner, *et al.*,[10] but whose limiting current is a function of light intensity. Because of its high ratio of dynamic-to-dc impedance, the device can be applied to conventional two-terminal photoconductor circuits (*i.e.*, bridges and dividers) and produce a considerably greater output voltage change for a given supply voltage than would a simple two-terminal photoconductor. Furthermore, the dependence of pinch-off current on the square of the light intensity has particular advantage in detecting small changes in relatively large light levels.

When connected in a conventional photocell circuit, application of suitable signals to the gate will perform switching and modulating functions. A reference voltage can be applied to the gate terminal which will determine the light intensity required to produce a particular output current for use in illumination control systems. Furthermore, suitable feedback networks between the gate and drain terminals can be used for frequency or temperature compensation, or for arbitrary shaping of the device characteristics.

Inasmuch as the field effect phototransistor has useful power gain, it can be used as an oscillator or as a signal amplifier. Phase shift oscillators employing one phototransistor have been constructed whose amplitude is a function of light intensity or which will oscillate only within a narrow range of incident light intensity. Signal amplifiers have been made which have light dependent gain, and which can be gated on or off with light intensity. Neon lamp relaxation oscillators using the cadmium sulfide transistor in place of the conventional resistor produce a very linear, constant amplitude sawtooth signal whose repetition rate can be varied with gate voltage and light intensity.

Unusual circuit functions can be performed by the device when signal information is contained in both the light modulation and gate voltage. For example, if the device is connected as a marginal oscillator, a discrete output occurs when the incident light intensity is modulated at the oscillator frequency. Furthermore, if the light modulation frequency is the same as that of the gate signal, synchronous phase discrimination results. Other specialized circuit functions can be performed by circuits which include two or more field effect phototransistors or by combining with other active circuit elements. The combination of this amplifying photoconductive device with electroluminescent devices may extend the utility of photoelectric circuits.[12]

PRACTICAL LIMITATIONS

The CdS field effect transistor does not compete with conventional junction transistors or vacuum tubes for general amplification applications. The major difficulties encountered in design of practical circuits using the device result from the relatively low mutual transconductance and high output impedance.

The mutual transconductance with zero gate voltage is approximately equal to the bulk conductance of the semiconductor slab, (5), and is a function of the carrier charge density, mobility and slab dimensions. Carrier density is the only parameter sufficiently flexible to permit a significant increase in transconductance. Increasing carrier density by a factor of 10 will increase G_m by that factor but will also increase pinch-off voltage by 10, pinch-off current by 100 and quiescent power dissipation by 1000. This results in impractical values for pinch-off current and voltage, and the power dissipation and electric field in the semiconductor slab may reach destructive limits of the material. Thus, G_m is limited to values of the order of 10 μmho in a CdS field effect transistor.

Both the output and input resistances of the CdS transistor are higher than are normally encountered with junction transistors and vacuum tubes. Efficient coupling to other active circuit elements is difficult and its advantageous use as an amplifying element is limited to low-frequency applications requiring high impedance levels (*i.e.*, photomultiplier or ion chamber signal amplification).

Improvement of the practical amplification characteristics can be achieved by increasing the carrier mobility of the slab material. This requires selection of a different material and would ultimately lead to an elemental or a group III-V compound semiconductor. However, CdS is very likely the best material for phototransistor application.

APPENDIX

A more general mathematical formulation is required to derive field effect equations for exponential charge distribution than is necessary for uniform[3] or linear graded[10] distributions. If the charge distribution is known, a relationship $V_g=f(h)$ can be derived from the gate potential as a function of the thickness of the space charge layer. Subsequent operations are simplified if the relation $h=g(V_g)$ can be found. This can be done for the uniform or linear graded case but is not possible for the exponential charge distribution case.

With exponential charge distribution of the form,

$$\rho(y) = \rho_0 \exp(-my), \tag{16}$$

the field in the y direction is assumed to be zero in the conducting channel ($h \leq y \leq a$) using Shockley's gradual approximation.[3]

$$\begin{aligned} E_y &= (I/K) \int \rho(y)dy = 0 \quad \text{at} \quad y = h \\ &= -(\rho_0/mk)(e^{-my} - e^{-mh}). \end{aligned} \tag{17}$$

The maximum field E_p required to pinch-off the conducting channel ($h=a$) exists at $y=0$:

$$E_p = (-\rho_0/mk)(1 - e^{-ma}). \tag{18}$$

The potential in the space charge region $V(y)$ is equal to the gate voltage V_g at $y=0$:

$$\begin{aligned} V(y) &= -\int E_y dy = V_g \quad \text{at} \quad y = 0 \\ &= (\rho_0/m^2K)(1 - e^{my} - mye^{-mh}) + V_g. \end{aligned} \tag{19}$$

With finite channel current, the potential in the conducting channel is a function of x, the distance from the source. The potential $V(x)$ cannot be derived directly for the exponential case but can be solved for $V(h)$ where h is a function of x:

$$\begin{aligned} V(h) &= V(y) \quad \text{at} \quad y = h \\ &= (\rho_0/m^2K)(1 - e^{-mh} - mhe^{-mh}) + V_g. \end{aligned} \tag{20}$$

With a gate-to-source potential V_g, a finite space charge layer thickness H_s will exist at $x=0$. Furthermore, $V(h)=0$ at $x=0$, so from (20),

$$V_g = (\rho_0/m^2K)(e^{-mH_s} + mH_s e^{-mH_s} - 1). \tag{21}$$

---

[12] S. K. Ghandhi, "Photoelectronic circuit applications," PROC. IRE, vol. 47, pp. 4–11; January, 1959.

The space charge layer thickness H_D at the drain end of the channel ($x=L$) is related to the gate voltage and the drain voltage V_D:

$$V_g - V_D = (-\rho_0/m^2K)(1 - e^{-mH_D} - mH_De^{-mH_D}). \quad (22)$$

The potential V_p required to pinch off the conducting channel is equal to $V_g - V_D$ at $H_D=a$:

$$V_p = (\rho_0/m^2K)(1 - e^{-ma} - mae^{-ma}). \quad (23)$$

The current in the conducting channel is constant at all values of x. The charge density represented by the free electrons in the conducting channel is assumed to be equal to $-\rho(y)$ in that region. The immobile holes generated in that region do not contribute to the channel conductivity. Additional free electrons forced into the conducting channel by the transverse field are rapidly distributed throughout the conducting system of the circuit and do not contribute significantly to the steady state channel current. Although the channel current is not a function of x, the current density J in the channel is a function of both x and y because of its dependence on $h(x)$ and $\rho(y)$:

$$J(x, y) = - E_x\mu\rho(y). \quad (24)$$

The channel current is obtained by integrating (24) and inserting the slab width c and the relationship $E_x = -dV(x)/dx$:

$$\begin{aligned} I &= c\mu(dV/dx)\int_h^a \rho(y)dy \\ &= (c\mu\rho_0/m)(e^{-mh} - e^{-ma})(dV/dx). \quad (25) \end{aligned}$$

Then, by substituting $dV(x)/dx = (dV/dh)(dh/dx)$ where $(dV/dh) = (\rho_0k/h)\exp(-mh)$ from (20),

$$I\int_0^L dx = \frac{c\mu\rho_0{}^2}{mK}\int_{H^s}^{H_D}(he^{-2mh} - he^{-m(a+h)})dh. \quad (26)$$

At pinch-off, $H_D=a$ and with zero gate voltage, $H_S=0$. The current I_p existing with these conditions is

$$I_p = (c\mu\rho_0{}^2/4m^3KL)\left[(2ma + 3)e^{-2ma} - 4e^{-ma} + 1\right]. \quad (27)$$

The mutual transconductance from gate to drain is

$$\begin{aligned} G_m = (\partial\,|\,/\partial V_g) &= (\partial\,|\,/\partial H_S)(\partial V_g/\partial H_S)^{-1} \\ &\quad + (\partial\,|\,/\partial H_D)(\partial V_g/\partial H_D)^{-1}. \quad (28) \end{aligned}$$

The partial derivatives are obtained from (21), (22), (26):

$$G_m = (c\mu\rho_0/mL)(e^{-mH_S} - e^{-mH_D}). \quad (29)$$

The bulk conductance of the slab is

$$G_0 = (\mu c/L)\int_0^a \rho(y)dy = (c\mu\rho_0/mL)(1 - e^{-ma}). \quad (30)$$

Note that with zero gate voltage, ($H_S=0$), and with $V_D = V_p$, ($H_D=a$), then $G_m = G_0$.

ACKNOWLEDGMENT

The cadmium sulfide field effect transistor program was initiated and coordinated by E. F. Weller. Additional appreciation is extended to Y. T. Sihvonen who supplied the CdS crystals and prepared the contacts on the first successful units, to J. W. Bergstrom and F. D. Bosco who further developed fabrication techniques, and to A. J. Gioia who assisted in parameter evaluation.

The Optimum Formula for the Gain of a Flow Graph or a Simple Derivation of Coates' Formula*

C. A. DESOER†, SENIOR MEMBER, IRE

Summary—Starting from the definition of a determinant and using a few of its elementary properties, this paper gives an independent derivation of the optimum formula for the gain of a flow graph. Thus, a simpler path is shown to Coates' important result. This paper is self-contained, so that no previous knowledge of flow graphs is required. For motivation, the reader is referred to some well known papers and books.

I. INTRODUCTION

MASON'S signal flow graphs[1,2] constitute a very useful tool for analysis of engineering problems, linear problems especially. The reason for their popularity and usefulness is that they display in a very intuitive manner the causal relationships between the several variables of the system under study. Many people have successfully used flow graph ideas in various fields.[1–9] Therefore, the publication of Mason's second paper[2] giving a systematic method for writing down almost by inspection the gain of a linear system was an important addition to the flow graph literature. Presently the state has been reached where a great many engineering schools include signal flow graphs in one of their senior courses.[5]

More recently, C. L. Coates[3] has shown that Mason's general gain formula is not the simplest expansion and has given a rigorous and lucid derivation of a new gain formula that is optimum in the sense that, *in general*, 1) no cancellations can occur between common factors of the numerator and denominator, and, 2) no cancellation can occur among the terms of the algebraic sums of the numerator and of the denominator.

The purpose of this paper is to present an independent derivation of Coates' formula. The author's hope is that this derivation is so simple that even seniors can grasp it![10] The only required background is the definition of a determinant. For the reader's convenience, this definition and the properties of determinants used in the derivation are listed in the Appendix.

For further background, motivation and examples, the reader is referred to the literature.[1–3,5] The present paper is self-contained in that it can be read independently of Mason's and Coates' papers.[1–3]

A word about the organization of the paper: There is a difference between Mason's and Coates' procedure for drawing the flow graph of a linear system. The difference, however, is very slight. The first five sections constitute an independent derivation of Coates' formula; they use exclusively Coates' procedure for associating a flow graph to a system of equations. Section VII discusses the difference between Mason's signal-flow graphs and Coates' flow graphs; it shows how, given one of them, the other may easily be obtained.

II. THE SET OF EQUATIONS AND ITS ASSOCIATED FLOW GRAPH

Our purpose is to solve by topological methods the set of linear algebraic equations

$$\sum_{j=1}^{n} a_{kj}x_j - b_k = 0 \qquad (k = 1, 2, \cdots, n). \qquad (1)$$

To this set of equations we shall associate a *flow graph* which is defined as follows:

> Definition 1—A *flow graph* is a set of weighted oriented branches which connect at nodes. That is, each branch has a positive direction and a weight, the branch gain.

The flow graph associated with (1) has n nodes and one source node. The case $n=2$ is illustrated in Fig. 1. The process of associating a flow graph to a set of equations is as follows:

1) To the source node is associated an input variable that is taken to be unity.
2) To each of the other nodes is associated one of the variables $x_1, x_2, \cdots, x_n$ of the set.

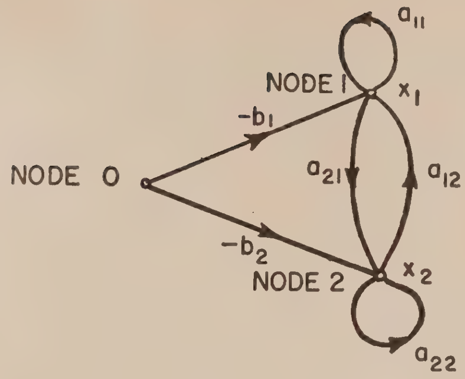

Fig. 1—Flow graph for the case of 2 equations with 2 unknowns.

3) Each node is labelled by one of the integers from 1 to n such that the node labelled k is associated with x_k. The source node is labelled 0.
4) If $a_{jk} \neq 0$, there is a branch directed from node k to node j with gain a_{jk}.
5) If $b_k \neq 0$, there is a branch connecting the source node 0 to node k. This branch is directed from 0 to k and its branch gain is $-b_k$.

This process describes how one goes from the equations to the graph. The reverse process, to obtain the equations from the graph, is very simple.

Consider Fig. 1 and concentrate on node 1. In order to write the equation associated with node 1, first consider all the branches coming into node 1; they are a_{11}, a_{12} and $-b_1$. The equation is obtained by equating to zero the sum of the products of their branch gains times the variables these branches originate from, viz:

$$a_{11} x_1 + a_{12} x_2 - b_1 \cdot 1 = 0.$$

Physically, we may think of these nodes as high gain operational amplifiers whose feedback loop is open. Because, in that case, if the output voltage is in the linear range of the amplifier, the sum of the currents into the input node must be very nearly zero.

At this stage an important point should be brought up. It is clear that to every set of equations such as (1) corresponds a flow graph and conversely. If, however, the order in which the equations appear in (1) is changed, the corresponding flow graph changes in a nontrivial manner. For example, to the set of equations

$$\begin{cases} \qquad \alpha x_2 + \beta x_3 = 0 \\ \gamma x_1 \qquad + \delta x_3 = b_1 \\ \epsilon x_1 + \eta x_2 \qquad = b_2 \end{cases}$$

corresponds the flow graph of Fig. 2.

Rearranging them as follows, we get a new set of equations

$$\begin{cases} \gamma x_1 \qquad + \delta x_3 = b_1 \\ \epsilon x_1 + \eta x_2 \qquad = b_2 \\ \qquad \alpha x_2 + \beta x_3 = 0 \end{cases}$$

and the flow graph of Fig. 3.

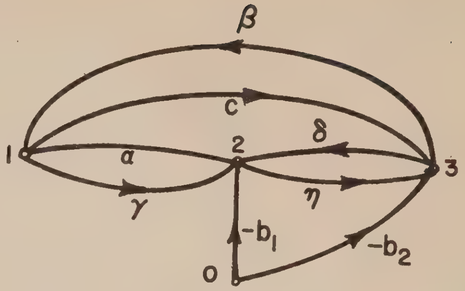

Fig. 2—Flow graph of the system (2).

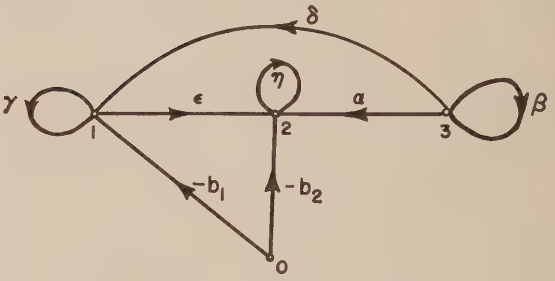

Fig. 3—Flow graph of the system (3).

Thus, once a system of linear homogeneous algebraic equations, such as (1), has been ordered in a fixed way, there is a one-to-one correspondence between the equations and the flow graph.

III. Algebraic Solution of (1)

If the matrix of the coefficients of the x_j's in (1) is nonsingular, the solution is given by

$$x_l = \frac{\sum_{k=1}^{n} \Delta_{kl} b_k}{\Delta} \qquad (l = 1, 2, \cdots, n) \qquad (2)$$

where

Δ is the determinant of the coefficient matrix (a_{ij}).
Δ_{kl} is the cofactor of the element of the kth row and lth column.

In the following we shall devise a topological method for evaluating Δ and products of the form $b_k \Delta_{kl}$.

IV. Topological Evaluation of Δ

In order to evaluate Δ by topological means, we require a few topological ideas; hence we define:

G to be the flow graph of the system (1), where the equations are taken in the order in which they appear;
G_0 to be the flow graph obtained from G by deleting the source node 0.

Definition 2—*A connection* of the flow graph G is a subgraph of G such that

1) each node of G is included,

2) each node has only one branch terminating to it and one branch originating from it.

Definition 3—*A directed loop* is a connected subgraph whose branches $b_1, b_2, \cdots, b_l$ can be ordered in such a way that

1) The tip of b_k is the origin of b_{k+1} $(k=1, 2, \cdots, l-1)$.
2) The origin of b_1 is the tip of b_l.
3) Each node along the directed loop is encountered only once.

Thus, a directed loop is precisely what is meant by a loop in the ordinary language. Fig. 4 illustrates the concept. Fig. 5(a) shows a flow graph G and Fig. 5(b) its five connections. It is clear that a connection is either a directed loop or a collection of nontouching directed loops (they are nontouching because of 2) in definition 2).

In addition, we shall need this definition:

Definition 4—*The connection-gain* of a connection of G is the product of the branch gains of the branches of that connection. It is denoted by $C(G)$.

The first link between the determinant Δ and the flow graph G is obtained by referring to the definition of a determinant:[4]

$$\Delta = \sum_P (\text{sgn } P) a_{1i_1} a_{2i_2} \cdots a_{ni_n} \qquad (3)$$

where the summation is taken over all the $n!$ permutations $P=(i_1, i_2, \cdots, i_n)$ of the integers, $1, 2, \cdots, n$ and (sgn P) is $+1$ or -1 depending on whether the permutation P is even or odd.[11]

Lemma 1: A product appears in (3) if and only if it is a connection-gain $C(G_0)$ of the flow graph G_0.

Proof: Recall that G_0 is the graph G with the source node 0 deleted. Consider a particular product $\prod$ in the sum (3). Let $\prod'$ be the set of all branches whose gain appear in the product $\prod$. Since $\prod$ is a product of factors a_{ki_k}, with k running from 1 to n, there is one and only one branch of $\prod'$ that terminates at each of the n nodes of G_0. Since $i_1, i_2, \cdots, i_n$ is a permutation of $1, 2, \cdots, n$, there is one and only one branch of $\prod'$ originating from each node of G_0. Hence $\prod'$ is a connection of G_0.

Conversely, given an arbitrary connection of G_0, since it contains by definition one branch terminating in each of the nodes of G_0 and one branch leaving each one of the same nodes, then its connection-gain can be written as

$$a_{1j_1} a_{2i_2} \cdots a_{ni_n}$$

where $i_1, i_2 \cdots, i_n$ is a permutation of the numbers $1, 2, \cdots, n$. Hence, it will appear as one of the products of the expansion (3).

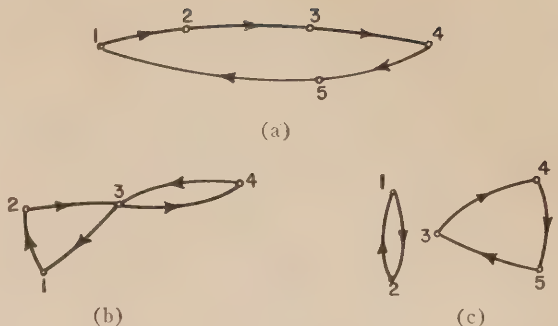

Fig. 4—(a) Example of a directed loop. (b) This is not a directed loop; when traversing the loop in the positive direction, node 3 is encountered more than once. (c) This is not a directed loop because it is not a connected subgraph.

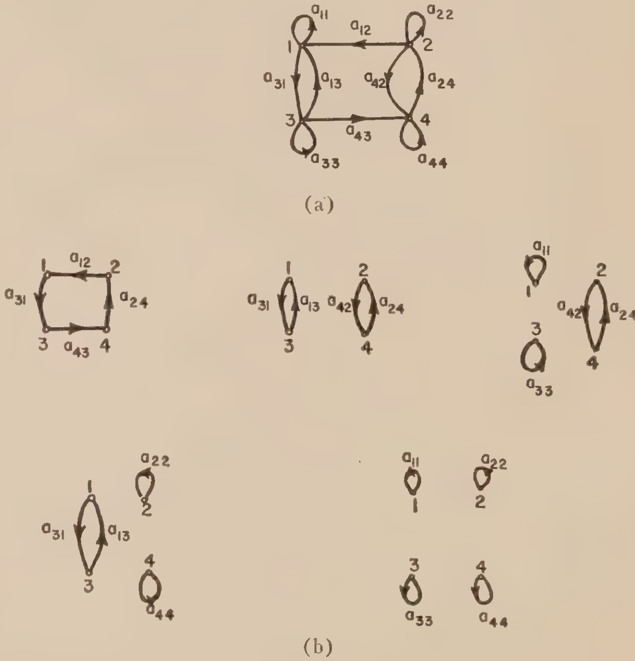

Fig. 5—(a) Flow graph associated with the matrix A. (b) The five connections of the flow graph shown in Fig. 5(a).

Thus by simply listing all the connections of G_0, as is done on Fig. 5, one obtains all the terms of the sum (3). The question of the signs remains. First let us make two rather obvious statements:

Statement 1—If, in a determinant, such as the one of the matrix A, any two rows are interchanged *and* the corresponding columns are also interchanged, the value of the determinant is not affected. (See Appendix, Property 3.)

Statement 2—Consider the system of equations (1) and its associated flow graph G. Suppose any two equations, say the ith and the kth, are interchanged and also the two variables located in the corresponding columns (*i.e.*, x_i and x_k): then to the resulting set of equations (1') corresponds a new flow graph G'. A little thought will show that G and G' are identical except for an interchange of the labels of the ith and kth node.

---

[11] The Appendix lists the three properties of determinants that will be used later.

The method required for specifying the sign of each term of (3) is obtained by the following reasoning:

Consider again a particular product $\prod$ of the sum (3) and its associated connection $\prod'$ of the graph G_0. $\prod'$ is a collection of directed loops; for simplicity let us assume that $\prod'$ consists of three nontouching directed loops having respectively n_1, n_2, n_3 nodes. Clearly, $n_1+n_2+n_3=n$, since all nodes of G_0 are included.

As a consequence of Statements 1 and 2 we can, without affecting any of the terms of the determinant expansion (3), relabel the nodes of $\prod'$ so that along the first directed loop of $\prod'$ as it is traversed in the positive direction one traverses the nodes $1, 2, \cdots, n_1$ in that order; and similarly for the other two directed loops. The branch gain product of the first directed loop is then

$$a_{1n_1}a_{21}a_{32}\cdots a_{n_1,n_1-1}.$$

Note that the factors of this product are ordered so that their row subscripts occur in their natural order as required by (3). Hence, the sign assigned to $\prod$ is that assigned to the permutation, defined by the column subscripts:

$$n_1, 1, 2, 3, \cdots, n_1-1; n_1+n_2, n_1+1, \cdots (n_1+n_2-1);$$
$$(n_1+n_2+n_3), (n_1+n_2+1), \cdots (n_1+n_2+n_3-1).$$

To rearrange this permutation in the natural order, $(n_1-1)+(n_2-1)+(n_3-1)=n-3$ interchanges between adjacent symbols are required. Hence, the sign of the permutation is $(-1)^{n-3}=(-1)^n(-1)^{+3}$. Note that there are three directed loops in the product $\prod$. It is clear that if the connection $\prod'$ had L directed loops the sign would have been $(-1)^{n+L}$.

Thus, we obtain the general

Theorem 1: The determinant Δ of the system (1) can be evaluated from its flow graph G by the formula

$$\Delta = (-1)^n \sum_p (-1)^{L_p} C(G_0)_p \tag{4}$$

where

L_p is the number of directed loops in the pth connection.

$C(G_0)_p$ is the connection gain of the pth connection.

G_0 is the flow graph G with the source node 0 deleted.

The summation of the connection gains $C(G_0)$ is taken over all connections of G_0.

Example: The determinant of the matrix associated with the graph of Fig. 5. From the graph G of Fig. 5, we obtain the matrix

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & 0 \\ 0 & a_{22} & 0 & a_{24} \\ a_{31} & 0 & a_{33} & 0 \\ 0 & a_{42} & a_{43} & a_{44} \end{bmatrix}.$$

From the five connections of G shown on the figure,

$$\det A = -a_{12}a_{24}a_{43}a_{31} + a_{13}a_{31}a_{42}a_{24} - a_{11}a_{33}a_{42}a_{24}$$
$$- a_{22}a_{44}a_{13}a_{31} + a_{11}a_{22}a_{33}a_{44}.$$

This expansion can also be obtained by Mason's method, but his general formula will give 25 terms which will eventually reduce to the five listed above.

V. EVALUATION OF THE NUMERATOR OF (2)

The numerator of (2) is a sum of terms all having the same form. Consider one of them in particular; say, $\Delta_{kl}b_k$. In other words, we are going to evaluate the numerator of (2) assuming that there is only one branch, with gain $-b_k$, connecting the source node 0 to the rest of the graph, as shown on Fig. 6(a). Since we know how to evaluate an $n\times n$ determinant by topological means, let us note that $\Delta_{kl}b_k$ is equal to the determinant obtained by replacing the lth column of Δ by a column of zero except for the element of the kth row, which is b_k.

$$\left|\begin{array}{c} 0 \\ 0 \\ b_k \\ 0 \\ \vdots \\ 0 \\ 0 \end{array}\right| \begin{array}{l} \\ \\ \leftarrow k\text{th row} \\ \\ \\ \\ \\ \end{array}$$

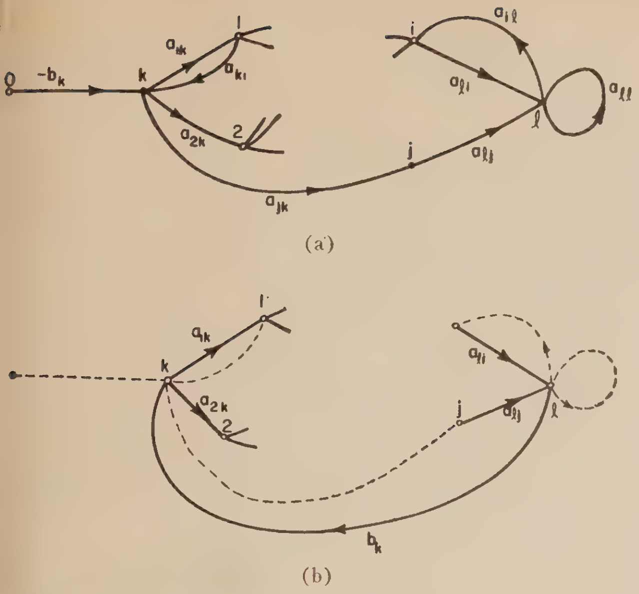
$$\uparrow l\text{th column}$$

This determinant will not change if all the elements of the kth row, with the single exception of b_k, are replaced by zero. The result is the determinant Δ'.

$$\Delta' = \left|\begin{array}{ccccc} & & 0 & & \\ & & \vdots & & \\ & & 0 & & \\ 0\ 0\cdots & & 0\ b_k & 0\cdots 0 \\ & & \vdots & & \\ & & 0 & & \\ & & 0 & & \end{array}\right| \leftarrow k\text{th row}$$

$$\uparrow l\text{th column}$$

In order to evaluate Δ' by topological means, let us note that the flow graph G' associated with Δ' is obtained from G_0 by: 1) deleting all branches leaving node l (the node with which the variable x_l, being sought, is associated); 2) deleting all branches coming into node k; and 3) adding the branch b_k oriented from node l to node k. This operation is illustrated on Figs. 6(a) and



(a)

(b)

Fig. 6—(a) Flow graph G. (b) Flow graph G' obtained from G by deleting all branches leaving node l, deleting all branches coming into node k and adding branch b_k oriented from node l to node k.

6(b). From (4),

$$b_k\Delta_{kl} = \Delta' = (-1)^n \sum_{\tau} (-1)^{L_\tau} C(G')_\tau$$

where

$C(G')_\tau$ is the connection gain of the τth connection of G'.

L_τ is the number of directed loops of the τth connection.

The summation is taken over all connections of G'.

In order to interpret this result in terms of the graph G, let us define as follows:

Definition 5—*A one-connection* from p to q of a flow graph G is a subgraph of G which includes all the nodes of G, and such that

1) no branch terminates at p and only one branch of the subgraph originates from p, thus:

2) no branch originates from q and only one branch of the subgraph terminates at q, thus:

3) all other included nodes have exactly one incoming and one outgoing branch.

An example of a set of one-connections is shown on Figs. 7 and 8. It is apparent from Fig. 8 that, in general, a one-connection is a forward path together with some directed loops.

Consider Fig. 6(b). Each one of the connections of G' includes the branch b_k because it is the only branch that leaves the lth node. In each one of these connections let us remove the origin of branch b_k from node l and place it at the source node 0 where it was originally in graph G. Finally, let us change the branch gain from b_k to $-b_k$. In each case the resulting configuration is a *one-connection* from 0 to l of flow graph G. Since by displacing the branch b_k one directed loop has been "opened," the number of directed loops in the one-connections of G is one less than that of the original connections of G'; this will result in a change of sign which will cancel the one caused by the change of sign of the branch gain b_k. Consequently,

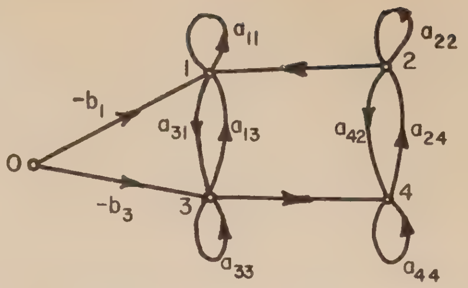


Fig. 7—Flow graph associated with the set of equations (6).

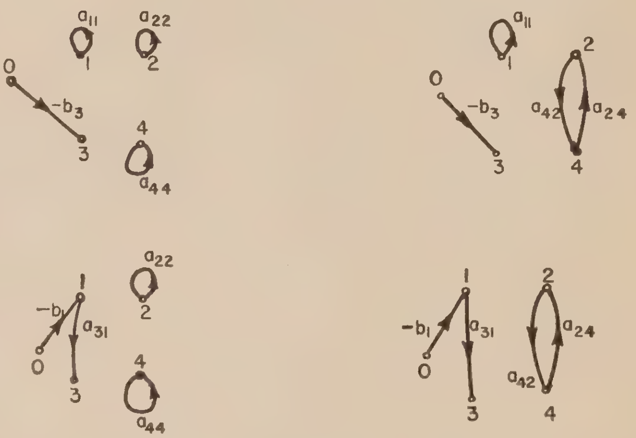

Fig. 8—The one-connections from 0 to 3 of the flow graph of Fig. 7.

$$b_k\Delta_{kl} = \Delta' = (-1)^n \sum_{\sigma} (-1)^{L_\sigma} C(G; 0 - l)_\sigma$$

where

$C(G; 0-l)_\sigma$ is the one-connection gain (*i.e.*, the product of the branch gains) of the σth one-connection from 0 to l of the flow graph G.

L_σ is the number of directed loops in the σth one-connection.

The summation is taken over all one-connections from 0 to l of G.

VI. General Formula

In general, there is more than one branch connecting the source node to the rest of the graph; obviously, in such cases the individual contributions of each such branch must be summed and the result takes this form:

Theorem 2: In order to solve for the variable x_l defined by the set of equations

$$\sum_{j=1}^{n} a_{kj}x_j = b_k \qquad (k = 1, 2, \cdots, n) \tag{1}$$

1) Set up the associated flow graph G as specified in Section II.
2) Draw all the connections of the flow graph G_0 (=graph G with source node 0 deleted) and list their connection gains: $C(G_0)_1$, $C(G_0)_2$, $\cdots$
3) Draw all the one-connections from the source node 0 to the node l of the graph G and list their one-connection gains: $C(G; 0-l)_1$, $C(G; 0-l)_2$, $\cdots$
4)

$$x_l = \frac{\sum_{\sigma} (-1)^{L_\sigma} C(G; 0 - l)_\sigma}{\sum_{\rho} (-1)^{L_\rho} C(G_0)_\rho} \tag{5}$$

where

L_σ = number of directed loops in the σth one-connection from 0 to l of the flow graph G.
L_ρ = number of directed loops in the ρth connection of G_0.
the summations are taken over all connections and one-connections from 0 to l of graphs G_0 and G respectively.

Example: Consider the system of equations,

$$\begin{cases} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 = b_1 \\ a_{22}x_2 + a_{24}x_4 = 0 \\ a_{31}x_1 + a_{33}x_3 = b_3 \\ a_{42}x_2 = a_{43}x_3 + a_{44}x_4 = 0. \end{cases} \tag{6}$$

Let us solve for x_3. The graph G is shown on Fig. 7. All the connections of G are listed in Fig. 5(b). The one-connections from 0 to 3 of G are shown on Fig. 8 Then, by (5), we have

$$x_3 = \frac{b_3a_{11}a_{22}a_{44} - b_3a_{11}a_{42}a_{24} - b_1a_{31}a_{22}a_{44} + b_1a_{31}a_{24}a_{42}}{\Delta}$$

where

$$\Delta = a_{11}a_{22}a_{33}a_{44} - a_{12}a_{24}a_{43}a_{31} + a_{13}a_{31}a_{42}a_{24} - a_{11}a_{33}a_{42}a_{24} - a_{22}a_{44}a_{13}a_{31}.$$

The general expression (5) calls for two important comments.

Comment 1—*In general,* there can be no cancellation of terms in the algebraic sums of either the numerator or the denominator of (5).

The reason for this is quite obvious: Since each term is a connection gain (a one-connection gain) of a connection (one-connection) distinct from all the other connections (one-connections) there can, in general, be no cancellations; for it would imply the existence of special relationships between the gains of various branches.

There is, however, one simplification that any engineer worth his salt would instinctively take advantage of. Suppose x_1 is to be computed and suppose there are some node variables x_{k_1}, x_{k_2}, $\cdots$, x_{k_m} that have no effect on x_1, then these nodes may be deleted from the graph when x_1 is computed.

This idea can be expressed precisely if the following definition is introduced:

Definition 6—*A forward path* from p to q of the flow graph G is a connected subgraph whose branches b_1, b_2, $\cdots$, b_l can be ordered such that

1) the tip of b_k is the origin of b_{k+1} ($k=1, 2, \cdots, l-1$)
2) each node of the forward path has only one branch terminating to it and one branch originating from it, with the exception of p and q which, respectively, have only one branch originating and terminating to them.

A forward path from p to q can be obtained from each one-connection from p to q by deleting from the one-connections all the directed loops.

The second comment takes the form

Comment 2—When solving for x_1, delete from the graph G all the nodes x_{k_1}, x_{k_2}, $\cdots$, x_{k_m} which have the property that there is no forward path that connects each one of them to x_1.

Example: Consider the system

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 &= 0 \\ a_{21}x_1 + a_{22}x_2 &= +b_2 \\ a_{32}x_2 + a_{33}x_3 + a_{34}x_4 &= 0 \\ a_{43}x_3 + a_{44}x_4 &= 0. \end{aligned}$$

The corresponding flow graph is shown in Fig. 9. It is obvious in this simple example, from the graph and from the equations, that the variables x_3 and x_4 may be disregarded in solving for x_1; also, there is no forward path from 3 to 1 and from 4 to 1.

A straightforward analysis shows that if the nodes $x_{k_1} \cdots x_{k_m}$ are not deleted, all the connection gains and the one-connection gains of (5) will have a common factor which will cancel from numerator and denominator. This leads to the very important conclusion that, provided the precaution of Comment 2 is taken into ac-

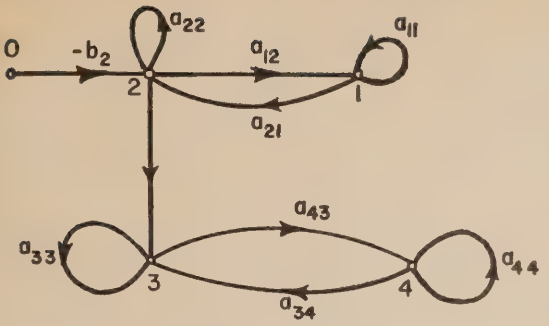

Fig. 9—Illustration of a flow graph that has no forward path from nodes 3 and 4 to node 1.

count, Theorem 2 gives the optimum gain formula for a flow graph.

Thus, the following important conclusion is reached: Given the problem of solving (1) by topological methods then, provided the Comment 2 is taken into account, the expression given in Theorem 2 is the simplest expression for the solution in terms of the b_k's and a_{ij}'s.

VII. The Relationship Between Signal-Flow Graphs (Mason) and Flow Graphs (Coates)

The process of association of a flow graph (Coates) to a set of equations has been described in detail in Section II. For reference let us note that the equations are written

$$\sum_{j=1}^{n} a_{kj}x_j = b_k \qquad (k = 1, 2, \cdots, n) \tag{1}$$

where

a_{kj} is the gain of the branch, directed from j to k, connecting node j to node k, and

$-b_k$ is the gain of the branch connecting the source node to node k.

Mason,[2] on the other hand, writes his equations thus:

$$\sum g_{kj}x_j = x_k + b_k \qquad (k = 1, 2, \cdots, n) \tag{7}$$

where

g_{kj} is the gain of the branch, directed from j to k, connecting node j to node k, and

$-b_k$ is the gain of the branch connecting the source node to node k.

Simply by looking at the equations we can see clearly that (1) and (7) will be identical if and only if

$$g_{kj} = a_{kj} \text{ if } k \neq j \quad \text{and} \quad g_{kk} - 1 = a_{kk}.$$

This gives the following rules:

1) To obtain a flow graph (Coates) from a given signal-flow graph (Mason), simply subtract one from the gain of each existing self loop and to each node of the signal-flow graph devoid of self loop, insert one with gain -1.

2) To obtain a signal-flow graph (Mason) from a flow graph (Coates), add unity to the gain of each existing self loop and to each node of the flow graph devoid of self loop, insert a self loop of gain $+1$.

Physically, we can interpret both graphs in terms of analog computer concepts:

A. Signal-Flow Graphs

Node variables x_j: potential of node j with respect to ground.

Gain g_{kj}: admittance of the branch connecting j to k, thus $g_{kj}x_j$ is a current entering node k.

Node: electronic summing amplifier: its output voltage is equal to the sum of the input currents:

$$x_k = \sum_{j=1}^{n} g_{kj}x_j - b_k \cdot 1.$$

Note that this summing amplifier does not invert the sign as is usually the case with analog computer amplifiers.

B. Flow Graphs

Node variables x_j: potential of node j with respect to ground.

Gain a_{kj}: admittance of the branch connecting j to k.

Node: operational amplifier with its feedback loop open; thus if the output voltage x_k is in the linear range, the sum of the input currents is negligibly small in view of the high gain of the amplifier; hence

$$\sum a_{kj}x_j - b_k \cdot 1 = 0.$$

Appendix

By definition, the determinant[4] of a matrix A is

$$\det A = \Delta = \sum_{P} (\operatorname{sgn} P) a_{1i_1} a_{2i_2} \cdots a_{ni_n}$$

where Σ/P denotes that the summation is taken only over the $n!$ permutations $i_1, i_2, \cdots, i_n$ of $1, 2, \cdots, n$ and (sgn P) is $+1$ or -1 depending on whether the permutation $i_1, i_2, \cdots, i_n$ is even or odd.

The key properties that are used in the paper are the following:

1) The interchange of any two adjacent symbols of a permutation changes the permutation into one of the opposite parity.

2) Exactly one element from each row and one element from each column appears in each term of the expansion of Δ.

3) If any two parallel lines (rows or columns) of A are interchanged, the determinant of the resulting matrix is $-\det A$.

A Broad-Band Cyclotron Resonance RF Detector Tube*

FRANKLIN M. TURNER†, MEMBER, IRE

Summary—**A tube is described which utilizes the cyclotron motion of electrons to provide a resonant system which is tuned by variation of the magnetic flux density. The amplitude of the cyclotron motion depends upon the relationship of the applied signal frequency and the electron cyclotron frequency; at resonance, the amplitude is maximum. Resonance is detected by shooting the spiraling electrons through a honey-comb type mesh grid; the current intercepted by the grid is greatest at resonance and is proportional to the RF signal power.**

The tube is a complete TRF receiver (less video amplifier) within one vacuum envelope. The resonant frequency is a linear function of solenoid current; the tube can be tuned over a wide frequency range (at least 10:1) with a single control. The characteristics of the device have been investigated for resonant frequencies from 65 to 650 mc; the sensitivity and 3-db RF bandwidth can be varied within limits; typical signal sensitivity is −45 dbm (500-kc video bandwidth) with a 4-mc 3-db RF bandwidth.

The measured characteristics and the theoretical predictions are in reasonable agreement.

INTRODUCTION

An electron beam, a static magnetic field parallel to the beam, and a perpendicular RF electric field may be combined to form a resonant system which can be tuned electronically over a wide frequency range. The application of this resonant system to the detection and frequency determination of RF signals had been explored by several investigators[1–3] and some tubes were constructed at Stanford University[4,5] prior to 1950. The sensitivity of these tubes was extremely poor, but it was nevertheless encouraging enough to support further efforts. From 1950 to 1954, tubes with much improved sensitivity were developed. Until recently, information concerning these tubes could not be widely disseminated due to security restrictions.

The cyclotron resonance detector tube, or cyclon detector tube, as it is sometimes designated, is essentially a nonamplifying resonant system followed by a detector; the resonant frequency of the system is the "cyclotron frequency"; the detector is a grid through which an electron beam is shot.

The cyclotron frequency is determined by the magnitude of the static magnetic field in which the electron beam is immersed. In one type of cyclotron resonance tube (the Spanatron) developed at Stanford,[6–10] the magnitude of the static magnetic field is made to vary spatially, in a known manner, across a sheet electron beam so that electrons in different sections of the beam have different resonant frequencies. The other, historically more recent, type consists of a pencil electron beam immersed in a uniform static magnetic field. Both types utilize the same basic phenomena. In the Spanatron, however, the frequency of an unknown signal is obtained by determining (with a detector grid) the section of the sheet beam that is in resonance with the unknown signal. Signal frequency is determined in the pencil beam tube by adjusting the magnitude of the uniform static magnetic field until resonance is indicated. This paper is concerned with the latter type of tube.

A photograph and a functional schematic representation of the cyclotron resonance detector tube to be described is shown in Figs. 1 and 2. A pencil electron beam is directed between the inner and outer conductors of a 50-ohm coaxial line. When an RF signal is applied to the coaxial line, an alternating electric field perpendicular to the beam is excited. If the RF frequency and the cyclotron frequency are nearly equal, the mutually perpendicular RF electric field and the uniform static magnetic field will cause individual electrons to spiral about axes parallel to the beam. The path radius of the spiralling electrons will be greatest when the RF fre-

quency, as viewed by an observer moving at the axial velocity of the electrons, is equal to the cyclotron frequency. To detect the spiral motion of the electrons, the beam is passed through a grid which is composed of many honeycomb-like cells (Fig. 3); some electrons are captured by the grid. If the path radii of the spiralling electrons are relatively small, most of the beam will pass through the detecting grid to the collector. If the path radii of the electrons are increased, fewer of the electrons in the beam will reach the collector. Thus, a current whose amplitude is sensitive to the path radii of the electrons may be obtained either from the detecting grid or from the collector.

The characteristics of a detecting grid were first investigated by Roberts[9] and Worcester;[10,11] Stewart subsequently completed a statistical theory of detector grid behavior. Stewart[12–15] also proposed and built cyclotron resonance detector tubes utilizing a coaxial line interaction structure. The tubes described here are refinements of Stewart's early models.

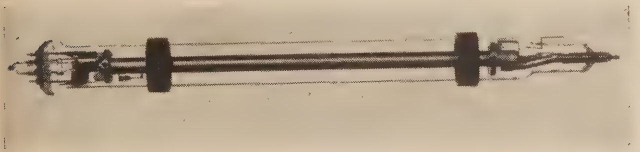

Fig. 1—Cyclotron resonance detector tube. Overall dimensions, $14\frac{5}{8}\times 1\frac{11}{32}$ inches.

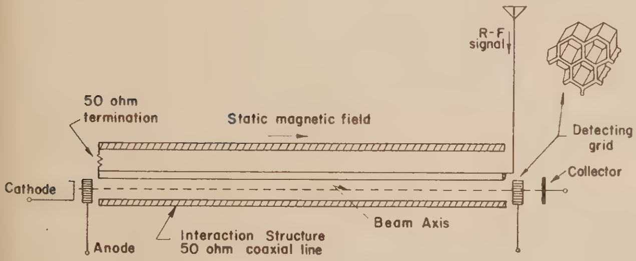

Fig. 2—Cyclotron resonance detector tube, functional schematic.

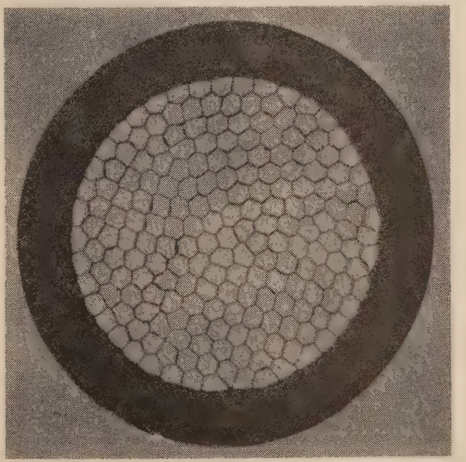

Fig. 3—Honey-comb detecting grid. Hexagonal cell diameter and depth, approximately 10 mils.

In the following portions of this paper a simplified analysis of the energy transfer from the RF electric field to the spiralling electrons will be presented, the mechanical details of the tube will be outlined, and the electrical characteristics, both predicted and measured, will be discussed. The theory of the detecting grid is presented elsewhere; only the observed characteristics of one particular grid are reported here.

DESCRIPTION OF CYCLOTRON RESONANCE DETECTOR TUBE

This section describes the mechanical details of a cyclotron resonance detector tube and typical operational procedures.

Construction of the tube is not difficult; many of the parts can be purchased commercially and those requiring fabrication are not complex. The tube is rugged, reliable, and simple to operate.

A major component of the tube is the 10-inch coaxial-line interaction structure. It is nonmagnetic stainless steel tubing; the inside diameter of the larger tubing is 0.36 inch, while the outside diameter of the smaller tubing is 0.15 inch. The outer coaxial cylinder is supported within the glass envelope by two support rings. Each support ring contains three synthetic sapphire balls (one of which is spring-loaded) which bear against the glass envelope. The tubing forming the inner coaxial conductor is supported at the gun end of the tube by an Aquadag coated glass bead. The glass bead, visible in Fig. 1, serves not only as a mechanical support, but also as the 50-ohm termination for the coaxial line.

The external RF connection to the tube is made at a coaxial Kovar seal near the collector. A short section of internal coaxial transmission line connects the interaction structure to the Kovar seal. RF is brought in at the collector end of the tube, not only to reduce the overall diameter of the tube, but also to keep the magnetic Kovar as far from the beam as possible.

A standard RCA cathode-heater assembly with a flat 0.12-inch oxide-coated cathode button provides the electron source. Both the anode and the detecting grid, which are mounted perpendicular to the beam, are of the type shown in Fig. 3. These grids, made available

through the courtesy of Varian Associates, have a cell diameter and depth of approximately 0.010 inch.

Typical applied potentials and resulting currents are: coaxial interaction structure, zero volts dc (outer conductor grounded); useful cathode voltage range, -3 to -15 volts; cathode current, 50–60 μa; collector current (in the absence of RF), 5–15 μa; dc collector potential, a few volts above ground (not critical); detecting grid, ground potential.

The beam voltage at which the tube is to be operated is chosen on the basis of RF bandwidth and sensitivity considerations (see Figs. 8 and 9); the anode potential is set one volt positive with respect to the cathode, and the tube's position in the magnetic field is adjusted to secure maximum collector current in the absence of a signal. A slight spatial re-alignment of the tube in the magnetic field, and adjustment of the anode potential, may be required to obtain maximum sensitivity when a test signal is applied.

The required magnetic field was generated by a wire-wound solenoid $16\frac{1}{2}$ inches in length and $4\frac{1}{2}$ inches in outside diameter. A reasonable amount of care must be exercised during construction of the solenoid to obtain winding uniformity. At a cyclotron frequency of 650 mc (232 gauss), the solenoid dissipated approximately 40 watts; a 1-ma change in the solenoid current varied the cyclotron frequency 3 mc.

Detection of Spiralling Electrons

The most satisfactory method discovered so far for detecting spiralling electrons is a honey-comb grid of the type shown in Fig. 3. It appears from geometrical considerations that, as a first approximation, the probability of electron interception by the detecting grid would be directly proportional to the radius of the electron's helical path. Observations indicated that this was not true; grid detection is more complicated than one might suspect. Consideration of the random phenomena created by the electrostatic field near the grid, and by thermal factors, suggested that a statistical approach to the problem might be fruitful. Both Worcester[10] and, more recently, Stewart[12,13,15] have analyzed detecting of grid behavior from a statistical viewpoint. Both these analyses correctly indicate that the change in intercepted current will be nearly proportional to the square of the signal-induced radius under small-signal conditions. That this is so may be inferred from Fig. 6 and (9). The actual sensitivity realized by the detecting grids is within a few db of that which is theoretically possible according to Stewart's analysis. For more details on the theoretical behavior of the honey-comb grids, the reader is referred to the references cited.

Theoretically the signal is negative at the detector grid (grid intercepts electrons) and positive at the collector; thus, it would seem, one would have a choice of video signal polarity. In practice, however, some detection occurs in the interaction structure; *i.e.*, some electrons spiral into the conductors of the RF transmission line. Near the lower frequency limit of the tube described, the detected signal at the grid may change polarity—due to interception of electrons in the interaction structure. Since the polarity of the signal at the collector is always the same, it was used rather than the grid signal.

Energy Transfer Mechanism

An electron entering the coaxial interaction structure with only an axial velocity would, in the absence of an RF signal, follow a straight-line trajectory parallel to the beam axis. However, should the electron acquire a velocity component transverse to the axial magnetic field, due to thermal emission effects, the RF field, or from any cause whatsoever, the electron trajectory will not be a straight line. The electron will instead spiral about a line parallel to the beam axis; in addition to its axial velocity, it will have acquired an angular velocity. Thus, the electron trajectory may be visualized as a helix of constant pitch with an axis parallel to the static axial magnetic field. The number of revolutions the spiralling electron completes each second (the cyclotron frequency) is uniquely determined by the magnetic flux density.

If the frequency of the RF field, as viewed by an observer moving at the axial velocity of the electron, is equal to the cyclotron frequency and if the phase relationship of the spiralling electron and the RF field is optimum, the electron will continuously gain energy from the transverse electric field. The radius of the spiralling electron will continuously increase as the electron moves through the interaction structure. If the observed RF frequency differs from the cyclotron frequency, the electron gains less energy, its path radius is less, and the current intercepted by the detector grid is less. Hence, the spiralling electrons form a resonant system. It is the purpose of the ensuing analysis to determine the characteristics of this resonant system.

In order to simplify the analysis, the terminated coaxial line structure used in the actual tube is replaced by a lossless, terminated parallel-plate transmission line in which all fringing fields are neglected. The parallel-plate structure and assumed coordinate system are shown in Fig. 4. The RF electric field is entirely in the y direction and independent of the x coordinate; the uniform static magnetic field is in the $+z$ direction only. A partial list of the symbols used follows (mks units are used unless otherwise noted).

B = axial magnetic flux density,
e = electronic charge,
E_y = instantaneous RF electric field $= E_0 \cos(\omega t + \beta z + \phi)$,
E_0 = maximum value of RF electric field,
m = electron mass,
u_0 = z-directed electron velocity,
v = RF phase velocity,
β = RF phase constant,

ϕ = phase angle relating value of RF electric field and angular position of electron at $t=0$, *i.e.*, $-E_0 e \cos\phi$ is force acting on electron at $t=0$,
ω = angular frequency of RF input ($\omega = 2\pi f$),
ω_c = cyclotron angular frequency ($\omega_c = 2\pi f_c$),
ω_k = angular frequency of RF input viewed by moving electron, and
τ = electron transit time through interaction space.

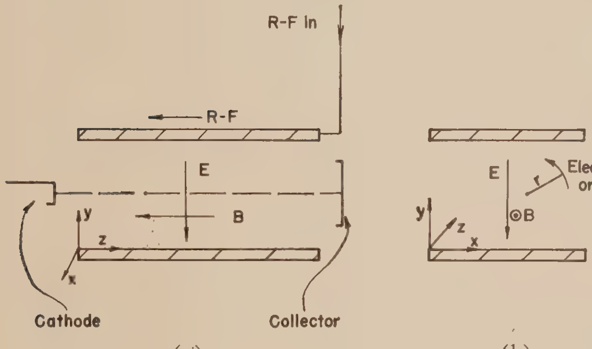
Neglecting the effects of other electrons, *i.e.*, space charge, it is well known that an electron having a velocity component perpendicular to a static magnetic field will, under equilibrium conditions, perform a circular motion having an angular velocity:

$$\omega_c = 2\pi f_c = \left| \frac{e}{m} B \right|,$$

where f_c = cyclotron frequency in cps.

The incremental energy gained by the orbiting electron from the RF electric field (see Figs. 4 and 5) is:

$$dW = \boldsymbol{F} \cdot \boldsymbol{ds} = -E_y e r \omega_c \cos \omega_c t \, dt. \tag{1}$$



(a) (b)

Fig. 4—Parallel-plate interaction structure, side and end views.

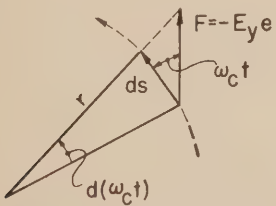


Fig. 5—Electron force diagram.

Since the energy of a spiralling electron is

$$W = \tfrac{1}{2} m r^2 \omega_c^2, \tag{2}$$

then

$$dW = m r \omega_c^2 dr.$$

Eliminating dW from (1) and (2),

$$dr = \frac{E_y}{B} \cos \omega_c t \, dt = \frac{E_0}{B} \cos(\omega t + \beta z + \phi) \cos \omega_c t \, dt. \tag{3}$$

The electron enters the interaction structure at $z = t = 0$. The z coordinate of the electron is $z = u_0 t$, so that $\beta z = \omega / v(u_0 t)$. Eq. (3) may be written

$$dr = \frac{E_0}{B} \cos(\omega_k t + \phi) \cos \omega_c t \, dt, \tag{4}$$

where

$$\omega_k \overset{\Delta}{=} \omega \left(1 + \frac{u_0}{v} \right).$$

If the amount of energy absorbed by the electron is small, E_0 can be assumed constant. Integrating (4) over the time interval 0 to τ, where τ is the electron transit time, one obtains

$$\begin{aligned} r &= \left| \frac{E_0 \tau}{2B} \left(\frac{\sin(\omega_c \tau - \omega_k \tau - \phi) + \sin \phi}{(\omega_c - \omega_k)\tau} + \frac{\sin(\omega_c \tau + \omega_k \tau + \phi) - \sin \phi}{(\omega_c + \omega_k)\tau} \right) + r_0 \right| \\ &= |r_s + r_0| . \end{aligned} \tag{5}$$

In this equation,

r = total electron path radius at $t = \tau$,
r_0 = initial electron path radius prior to electronic interaction, and
r_s = component of electron path radius due to electronic interaction with RF field.

The absolute magnitude of (5) is taken since a negative value of r has no physical significance.

If the assumption is made that $(\omega_c + \omega_k) \gg |\omega_c - \omega_k|$, (5) can be written

$$r = \left| \frac{E_0 \tau}{2B} \, \frac{\sin \frac{\Delta\omega\tau}{2}}{\frac{\Delta\omega\tau}{2}} \cos\left(\phi - \frac{\Delta\omega\tau}{2} \pm 2n\pi \right) + r_0 \right|,$$

$$n = 0, 1, 2, \cdots, \quad \text{and} \quad \Delta\omega = \omega_c - \omega_k. \tag{6}$$

Application of the assumption noted invalidates (6) near the zeros of the $(\sin \Delta\omega\tau/2)/(\Delta\omega\tau/2)$ term. The equation can be used, however, to describe the maximum value of $|r|$ as a function of the pertinent variables.

Presumably all values of ϕ are possible in an actual tube so that the maximum possible electron path radius as a function of $\Delta\omega\tau$ is observed by the detecting grid. This radius is

$$r = \left| \frac{E_0 \tau}{2B} \left| \frac{\sin \frac{\Delta\omega\tau}{2}}{\frac{\Delta\omega\tau}{2}} \right| + r_0 \right| . \tag{7}$$

Maximum radius is obtained at $\Delta\omega = 0$; resonance, therefore, occurs when $\omega_c = \omega_k$, *i.e.*, when

$$f_c = f\left(1 + \frac{u_0}{v}\right). \tag{8}$$

The factor $(1 + u_0/v)$ represents the increase in the signal frequency (f) as "seen" by the electron due to the Doppler effect. If the RF wave on the parallel-plate transmission line were a standing-wave rather than a traveling-wave, resonance would occur at $f = f_c$.

The electron path radius at resonance is

$$r_m = \left| \frac{E_0\tau}{2B} + r_0 \right|. \tag{9}$$

Taking the ratio of (7) and (9) gives the relative electron-path radius with respect to the resonant radius. Assuming that the initial radius r_0 is small compared to the signal induced radius, this ratio becomes

$$\frac{r}{r_m} = \left| \frac{\sin \frac{\Delta\omega\tau}{2}}{\frac{\Delta\omega\tau}{2}} \right|. \tag{10}$$

Both experimental and theoretical considerations indicate that the detecting grid output varies as the square of the electron path radius. Squaring (10), therefore, gives the relative response curve of the device as the signal frequency varies. If the signal frequency is held constant, and the magnetic field (cyclotron frequency) is varied, the response curve is given by the square of (10), provided $\Delta\omega$/resonant angular frequency $\ll 1$.

Eq. (10) has decreased to 0.707 of its maximum value when $\Delta\omega\tau/2 = 1.39$; the 3-db bandwidth is, therefore,

$$\Delta f_{3\text{db}} = \frac{\Delta\omega}{\pi} = \frac{2.78}{\pi\tau}\cdot \tag{11}$$

Since the energy transferred to a resonant electron is given by $\frac{1}{2}m(E_0\tau/2B)^2\omega_c^2$, the power transferred to a beam is

$$P_c = \frac{e}{m} I \frac{(E_0\tau)^2}{8}, \tag{12}$$

where I = beam current, and P_c = power transferred to the beam.

It will be noted from the preceding analysis that the resonant electron path radius is proportional to the product of the peak value of RF field and electron transit time [see (9)]. Once one has decided upon an interaction structure, the peak value of the transverse electric field is fixed for a given signal power input. Transit time, however, can be controlled by adjustment of the beam voltage.

Increasing the electron transit time (decreasing the beam voltage) decreases the signal power required to attain a given resonant radius, and at the same time, decreases the 3-db bandwidth [see (11)]. As one might suspect, there is a practical limit as to how far the transit time may be increased. Experimentally, the minimum useful beam voltage has been determined to be approximately 3.5 volts for the 10-inch coaxial-tube line. This corresponds to a minimum 3-db bandwidth of about 4 mc. The 3-db bandwidth, as indicated by (11), has been found to be essentially independent of the resonant frequency, at least over the 10:1 frequency range investigated. Similarly, the power coupled to the beam at resonance is independent of frequency. Eq. (12) also indicates that the frequency range over which power can be satisfactorily coupled to the beam is determined only by the frequency characteristics of the interaction structure.

In arriving at (10), which describes the relative electron path radius, it was assumed that all values of ϕ are possible because the time-relationship of electron entry and the peak RF field is random. Some electrons will, therefore, always acquire the maximum possible energy as the signal frequency varies about the cyclotron frequency. The response for off-resonance frequencies would, under these conditions, decrease in relative amplitude at the slowest possible rate; *i.e.*, the response given by (10) has the worst possible selectivity for this resonant system.

One is therefore led to inquire as to the possibility of obtaining a more selective response characteristic. Such a possibility exists; for $\phi = 0$, (10) becomes:

$$\frac{r}{r_m} = \left| \frac{\sin \Delta\omega\tau}{\Delta\omega\tau} \right|, \tag{13}$$

where r_m is given by (9). The 3-db bandwidth obtained for $\phi = 0$ is exactly one-half of that given by (11).

CHARACTERISTICS OF THE CYCLOTRON RESONANCE DETECTOR TUBE

The tube responds to CW, AM, and FM signals; for convenience, however, pulsed signals were generally used in determining the characteristics described in this section.

The relative amplitude of detected RF pulses as a function of the peak RF power input is shown in Fig. 6. The detection is square law over the region where the slope of the curve is one, *i.e.*, over a power input range of 20 db. Saturation occurs at approximately 1/10 of a milliwatt; the input RF power dynamic range is approximately 35 db. The data for Fig. 6 were taken at resonance with a beam voltage of 4.0 volts at an RF input frequency of 230 mc. The detector characteristic observed at other frequencies (100 and 500 mc) is not significantly different from that shown in Fig. 6.

The relative response curve for the tube is shown in Fig. 7; the solid curve represents the actual response, while the dashed curves are the envelopes of the two the-

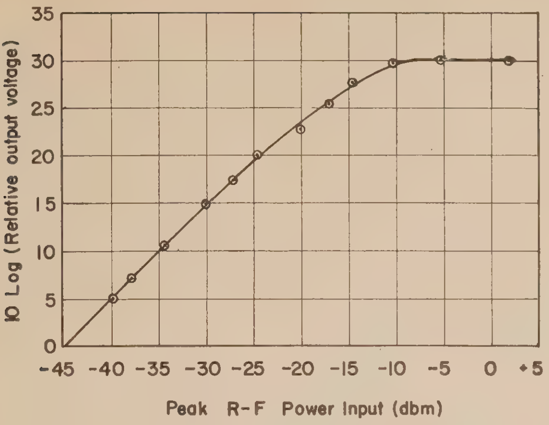

Fig. 6—Grid detector characteristic.

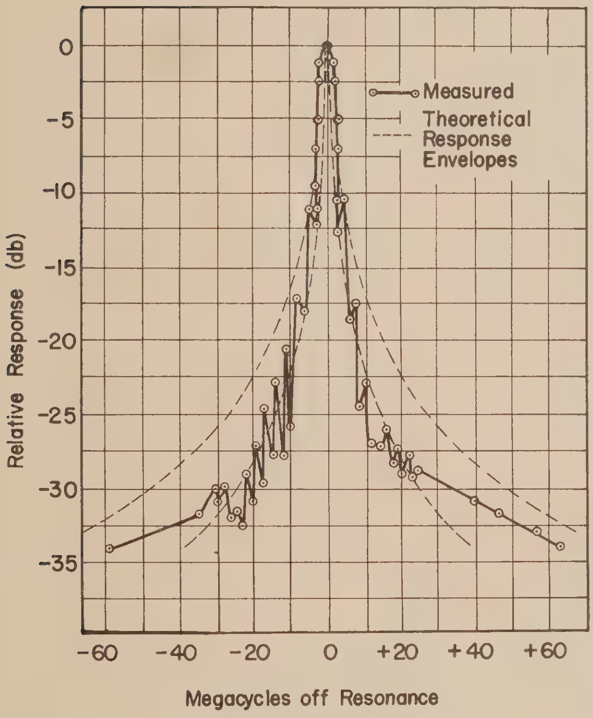

Fig. 7—Cyclotron resonance relative response curve.

oretical response characteristics obtained from (10) and (13), assuming the detector grid responds to the square of the relative electron path radius. Due to the assumption noted in connection with (6), only the envelope of the theoretical responses (curve through maximum values of $|r/r_m|^2$) is shown in Fig. 7. The outer dashed curve is (10) squared and represents the envelope of the response one would expect to obtain; the inner, more sharply resonant, dashed curve is shown merely to indicate a more desirable response which is, at least theoretically, obtainable. Inspection of Fig. 7 shows that the agreement between experiment and theory is reasonable, but by no means perfect. Assumptions involved in the analysis and the experimental error probably account for the discrepancy.

The characteristic shown in Fig. 7 is typical of the response curves observed for resonant frequencies greater than 100 mc. In the region of 100 mc and below, the response becomes noticeably asymmetric for reasons not clearly understood.

The selectivity of the resonant system is not particularly impressive: the 30-db/3-db bandwidth ratio is only about 14. One obvious means of improving the selectivity is to provide RF pre-selection ahead of the tube. For operation over an extensive frequency range, as well as for ease in tracking, the pre-selector also probably should be a device which utilizes the cyclotron resonance phenomena. Perhaps a device patterned after the Cuccia electron coupler[16,17]—but with wide-band transmission line input and output interaction-structures—would be an effective pre-selector.

The 3-db RF bandwidth as a function of beam voltage is shown in Fig. 8. The solid curve is plotted from measured data; the dashed curve is calculated from (11). The electron transit-time required for substitution in (11) was calculated on the basis of a 10-inch interaction length and an average axial velocity, u_0, given by the relation $\frac{1}{2}mu_0^2 = eV$, where V is the cathode voltage. The predicted and measured curves are nearly parallel for beam voltages greater than 3.5 volts, thus, at least qualitatively, providing verification of (11) in this region.

The abrupt change in the general trend of the solid curve in Fig. 8 at beam voltages of 3.5 volts and less is correlated with a similar change in the sensitivity-beam voltage characteristic (see Fig. 9).

Since the electron path radius at resonance is proportional to the transit time [see (9)], it is to be expected that sensitivity will decrease with an increase in beam voltage. In Fig. 9 the tangential signal sensitivity for a 1-μsec pulse (500-kc video bandwidth[18]) is plotted as a function of beam voltage. At beam voltages of 3.5 volts and less, the general trend of the curve is reversed: in this region the tube also becomes acutely sensitive to minor changes in operating conditions. It is customary, therefore, to operate the tube at a beam voltage of four or even five volts when maximum sensitivity is desired.

The sensitivity-beam voltage characteristic is essentially independent of frequency, at least over the 65–650-mc range examined. The ordinate (sensitivity) will change with resonant frequency. The shape of the curve and of the abscissa, however, remain intrinsically unchanged.

[17] C. L. Cuccia, "The electron coupler—a developmental tube for amplitude modulation and power control at ultra-high frequencies—Part II," *RCA Rev.*, vol. 14, pp. 72–99; March, 1953.

[18] The post-detection (video) amplifier bandwidth must be chosen so as to amplify the detected modulation with satisfactory fidelity. This bandwidth will in turn affect the video amplifier noise and thereby the minimum detectable RF signal.

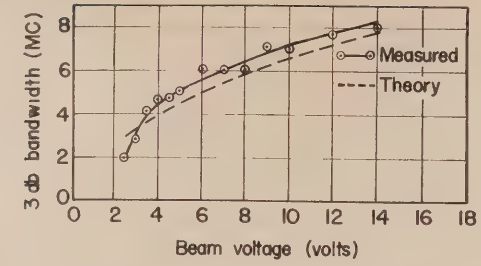

Fig. 8—3-db RF bandwidth vs beam voltage.

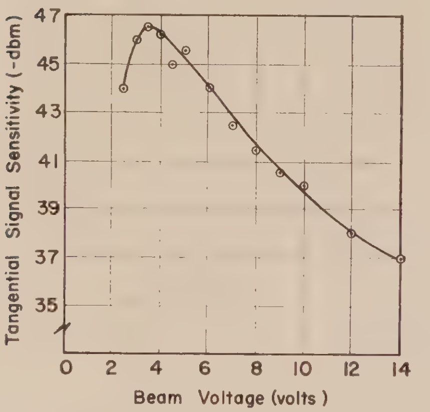

Fig. 9—Tangential signal sensitivity vs beam voltage, 500-kc video bandwidth.

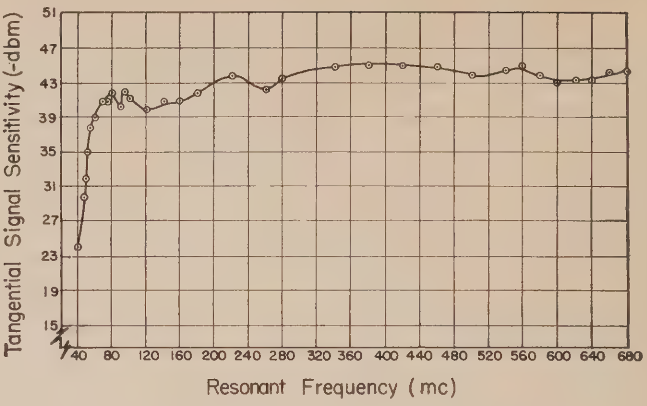

Fig. 10—Tangential signal sensitivity vs resonant frequency, 500-kc video bandwidth and 5-mc RF bandwidth.

The wide frequency range over which the cyclotron resonance detector tube can be operated is indicated in Fig. 10. The resonant frequency was varied by changing the current in the solenoid windings; no other adjustment was made. The sensitivity gave no sign of decreasing above 680 mc; data were not taken at higher frequencies because of solenoid dissipation. The sensitivity shown in Fig. 10 is for an RF bandwidth of 5 mc (5-volt beam) and for a 1-μsec pulse (500-kc video bandwidth).

The poor sensitivity of the tube at the lower frequencies appears to be due primarily to beam transmission difficulties. At 56 mc, for example, the axial magnetic flux density required for resonance is only about 20 gauss. The useful low-frequency limit for these tubes would appear to be about 65 mc; operation near this low frequency limit requires that the solenoid be carefully shielded from the earth's magnetic field.

RF pre-amplification can be used to improve upon the basic sensitivity of the cyclotron resonance tubes. Low-noise, wide-band distributed amplifiers have been employed to obtain tangential signal sensitivities of −90 to −95 dbm over wide frequency ranges.

One of the unusual features of these tubes, possibly unique, is the electronically variable RF 3-db bandwidth. Fig. 8 would indicate that one need only vary the beam voltage to attain a desired 3-db bandwidth. It is true that the beam voltage controls the bandwidth, but usually a slight adjustment of anode voltage (and possibly of the tube's spatial alignment) is required to obtain maximum sensitivity following a change in the beam voltage. At most, the adjustments would take a few minutes; it might, however, be useful if one were able to change the bandwidth rapidly. This can be accomplished by distorting the axial magnetic field so as to achieve an effect analogous to staggered tuning.

The interaction structure of the cyclotron resonance tube and the magnetic field in which the tube is immersed are analogous to a resonant circuit which is tuned by varying the magnetic flux density. If the magnetic flux density over one-half the length of the interaction structure is different from that of the other half, the situation is analogous to that of two tuned circuits of different resonant frequencies connected in series. (In bandpass-amplifier theory, this combination would be called a "staggered pair.") Perhaps the simplest way to achieve a staggered magnetic field is to add a second winding to the solenoid which is wound clockwise for half the length of the solenoid and counter-clockwise for the remaining half. A current flowing in this winding will produce, ideally, an axial magnetic field which adds to the main field over one-half the length of the solenoid and subtracts from the main field over the other half. Since the added winding need only produce a magnetic field on the order of one or two gauss, the additional power required is negligible.

With the proper current flowing in the additional solenoid winding, a response curve with three peaks is obtained (see insert of Fig. 11). This response is nearly independent of the resonant frequency, as long as the beam voltage and the current in the additional winding remain unchanged. To change from the response of Fig. 7 to the three-peaked response of Fig. 11, one need only throw a switch to send a predetermined current through the additional winding. If the beam voltage is changed by more than 10 per cent, it is necessary to adjust the value of this current to obtain maximum results.

In Fig. 11 the 3-db bandwidths for the uniform and staggered magnetic fields are compared. The bandwidth is increased by a factor of approximately 3 (theoreti-

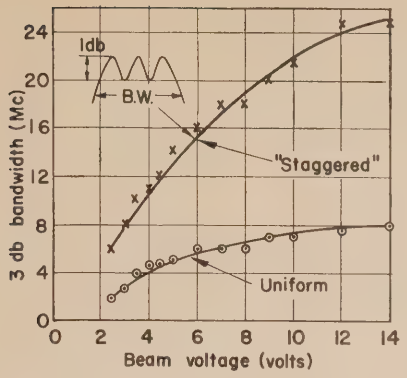

Fig. 11—3-db RF bandwidth vs beam voltage, uniform and "staggered" magnetic field.

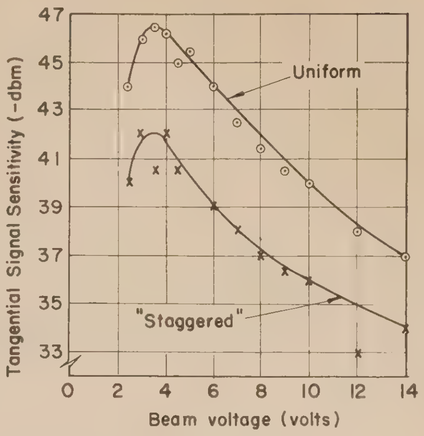

Fig. 12—Tangential signal sensitivity vs beam voltage, uniform and "staggered" magnetic field.

cally, 2.8) when the magnetic field is staggered. The increased bandwidth is acquired at the expense of sensitivity; the reduction of sensitivity (see Fig. 12) varies between 3 and 5 db depending upon the beam voltage.

The cyclotron resonance tubes are relatively immune to damage by high RF powers. Permanent damage is most likely to occur first at the terminating resistance. A small change in the value of the coaxial line termination is not detrimental. However, a large VSWR on the coaxial line would narrow the frequency range over which satisfactory sensitivity could be obtained. RF power of a magnitude far less than that which could cause any possible physical damage does, however, produce undesirable spurious responses.

If the RF input is sufficient to saturate the tube, that is, if it is greater than −10 dbm, spurious responses—which have no apparent relationship to the applied signal frequency—appear over a wide frequency range. These responses are at least 30 db below the peak of the main response and are easily identifiable. A second type of spurious response—which may have more serious consequences—is observed when the input power exceeds approximately −20 dbm. This response occurs when the cyclotron frequency is approximately half of the signal frequency: its amplitude is also at least 30 db below the main response, but the shape of its response-curve appears to be very similar to that of the main response (Fig. 7); hence, it can be mistaken for a weak legitimate signal.

CONCLUSIONS

The idealized and simplified theory of energy transfer presented in this paper—along with the results from an analysis of detecting grid behavior[13]—is sufficient to predict many of the characteristics of a cyclotron resonance detector tube.

The cyclotron resonance tubes are characterized by an extremely broad frequency range (at least 10:1) over which operation is possible. Resonance may be electronically varied; tuning is linear and may be accomplished either with a single manual control, or by periodic variation of the solenoid current (automatic frequency scanning). The sensitivity, RF bandwidth, dynamic range, and selectivity of this device should prove adequate for many purposes.

ACKNOWLEDGMENT

The author wishes to express his appreciation to L. D. Buchmiller for his suggestions and comments concerning the material in this manuscript. The author also desires to acknowledge the skill of H. R. Andrews, who constructed the tubes described.

The Stanford-developed cyclotron resonance tubes could not have been brought to their present state without the contributions of many people. In particular, the work of S. F. Kaisel, L. A. Roberts, W. G. Worcester, and J. L. Stewart was indispensable.

Anomalies in the Absorption of Radio Waves by Atmospheric Gases*

A. W. STRAITON†, FELLOW, IRE AND C. W. TOLBERT†, SENIOR MEMBER, IRE

Summary—**This paper summarizes recent measurements of the attenuation of radio waves by atmospheric gases and compares the measured losses with those predicted by Van Vleck. Reasonably good agreement has been noted between the predicted and measured losses for oxygen, but the measured loss for water vapor is considerably in excess of that predicted. Various factors which may influence this discrepancy are discussed.**

INTRODUCTION

In two classic papers in 1947, Van Vleck[1,2] evaluated the experimental evidence available on the absorption characteristics of atmospheric gases and predicted the magnitude of the attenuation of radio waves due to oxygen and water vapor. These papers have served as the starting point for most subsequent work in the field and the numerical predictions have been used frequently to estimate propagation losses.

The absorption of energy from a radio wave by atmospheric gases is due to the transition from one molecular rotation energy level to another caused by the electromagnetic wave. For gases at very low pressures, this energy change is associated with a very narrow band of frequencies. For increased pressures, the energy is absorbed over a wider range. The frequency dependence of microwave absorption was given by Van Vleck and Weisskopf[3] and the Van Vleck-Weisskopf equation as given in the Appendix has been the most commonly used means of predicting atmospheric losses.

Two critical constants are involved in each energy level transition. The first of these is the frequency associated with the energy transition. This may be determined from a knowledge of the energy levels or from direct measurement. Since the energy differences are very small for absorption lines in the microwave spectrum, the error involved in taking the difference of two nearly equal values is large. For this reason, direct measurement of resonant frequency is preferable where possible.

The second critical number is the line breadth constant associated with the frequency spread of the absorption. This value should be determined by direct measurement for the most reliable results.

VAN VLECK'S CHOICE OF LINE BREADTH CONSTANT

At the time of Van Vleck's papers, no propagation test had been made through the actual atmosphere in the millimeter wavelength region, and only a very few quantitative data were available in the centimeter region. On the basis of infrared studies, it had been possible to establish the molecular energy levels and the frequencies associated with their differences.

Oxygen losses in the millimeter spectrum result from the interaction of the magnetic moment of the O_2 molecule with the electromagnetic field. Transitions to the ground state occur with corresponding wavelengths grouped around 0.5 cm, and with one transition wavelength at 0.25 cm. In addition, nonresonant or Debye absorption provides a continuous spectrum of loss.

For line breadth constants of 0.05 or greater, the lines in the 5-mm wavelength band blend together to form a single line. On the basis of measurement of oxygen losses near 5 mm in waveguides by Berringer,[4] Van Vleck concludes that the appropriate line breadth constant should be 0.02 cm^{-1} at one atmosphere. The losses calculated, using this constant, were plotted in Fig. 1. The attenuation curve is somewhat irregular at the first peak but the details are masked by the log-log scale.

Measurements by Lamont[5] of oxygen losses around 5 mm through the actual atmosphere were found to be adequately explained by the use of the line breadth of 0.02 cm^{-1}. Laboratory measurements by Strandberg, *et al.*,[6] on pure oxygen and oxygen-nitrogen mixtures agreed with a line breadth constant between 0.015 and 0.02 cm^{-1}.

For water vapor, one line occurs near 1.35 cm and one at 1.63 mm. In addition, there are a vast array of lines in the near millimeter region. Ghosh and Edwards[7] have listed 588 of these absorption lines. Of these, 149 with significant line strength have wavelengths between 0.05 and 1.0 mm. The direct measurement of the line breadth constant has been possible only for the 1.35-cm line. Van Vleck concluded, on the basis of resonant cavity measurements by Becker and Autler[8] at Columbia Uni-

versity, that this line breadth constant should be approximately 0.1 cm^{-1}. The assumption was made that this line breadth constant was the same for all water vapor lines and the spectral distribution of the water vapor losses was calculated. This theoretical attenuation as a function of frequency is shown in Fig. 2 for the line breadth constant of 0.1 cm^{-1} and also for a line breadth constant of 0.27 cm^{-1}.

Difficulties in Direct Transmission Loss Measurements

It is rather surprising that there are very few reports in the technical literature of quantitative measurements of absorption by atmospheric gases on actual transmission paths. Dicke's[9] radiometric measurement of the sun at 1, 1.25 and 1.50 cm provided estimates of the water vapor loss, but required a knowledge of the water vapor distribution with height which can only be approximated.

The problem in millimeter measurements has been the lack of generators of sufficient power to make actual transmission tests. In recent years, however, improvements in millimeter techniques have extended the range over which propagation measurements could be made, and data are available at a good many frequencies.

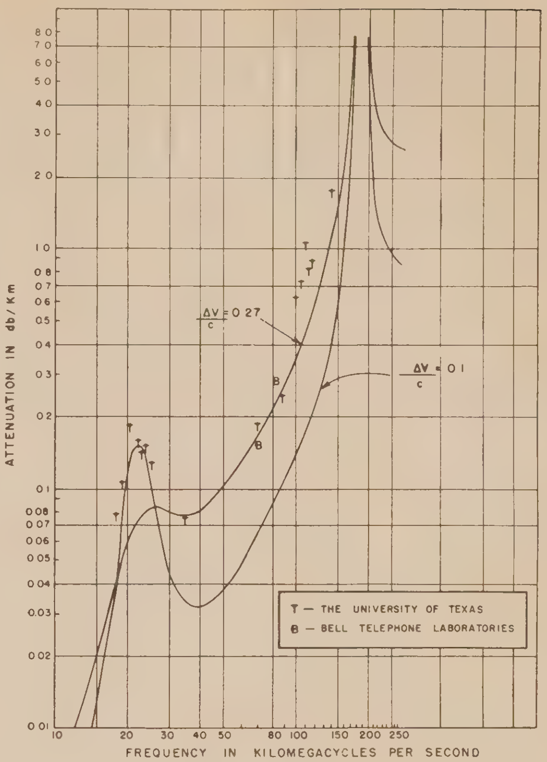

Fig. 2—Water vapor attenuation for 7.5 g/m^3.

In addition to the equipment problems, there are a number of difficulties encountered in the propagation tests that require them to be made with a great deal of care.

The general procedure for making the tests is to observe the signal level on a number of days and to plot this signal strength as a function of water vapor content in the atmosphere. The slope of this line provides the water vapor losses and the ordinate or y-axis intercept provides the oxygen loss.

Inhomogeneity in the water vapor content is known to exist both on small and large scales. In practice, the water vapor concentration is measured at both ends of the path and compared to data available from the U. S. Weather Bureau. The process of time averaging of the measurements and the use of many samples gives a measure of the variation of loss with water vapor concentration which is felt to be quite reliable.

Another annoyance in the measurement is the fact that considerable scintillation in the signal level may occur. The magnitude of these fluctuations is greater than can be explained by variations in the mean water vapor density and therefore must be attributed to refraction effects. The signal chosen as representative of a given sampling period is the mean level.

A third problem in propagation measurements is the presence of precipitation along the path. Care must be taken that the absorption measurements are made at a time when the atmosphere is free of rain or solid particulate matter.

Summary of Recent Measurements

During recent years, improvements in generators and components have made possible a number of absorption measurements through the actual atmosphere. Such measurements have been made by Bell Telephone Laboratories[10] at wavelengths in the 5- to 6-mm region and at 4.3 and 3.7 mm. Similar measurements have been made by The University of Texas Electrical Engineering Research Laboratory at wavelengths in the range from 1.2 to 1.7 cm, at 8.6 mm, 4.3 mm, 3.35 mm, 2.15 mm, and at a number of wavelengths in the region from 2.5 to 3 mm.[11] The results of all these measurements have been plotted on Figs. 1 and 2 for comparison with the Van Vleck curves.

The points plotted on the log-log curves tend to give the impression of a closer agreement between the measured and theoretical values than actually exists. Some details of the spectrum will be considered later.

From Fig. 1, it is seen that the agreement between the measured and calculated values of absorption for oxygen are reasonably good, but for reasons pointed out later, care should be exercised in extrapolating the data to points very far from the frequencies at which they were measured.

From Fig. 2, it is seen that the water vapor losses are consistently larger than those predicted by Van Vleck for a line breadth constant of 0.1 cm^{-1}. These deviations will be discussed in greater detail in the following sections.

Residual Effect of Submillimeter Water Vapor Lines

In those sections of the microwave spectrum far removed from a water vapor absorption line, the attenuation is primarily controlled by the skirts of the submillimeter lines. This effect is shown in Fig. 3.[12] The line numbers are in the order of increasing frequency. It is noted in the frequency range from 50 to 130 kmc that the first 12 lines make a relatively small contribution to the total absorption and that line numbers 21 through 76 make approximately the same contribution as the first 20 lines.

The curves of Fig. 3 are based on the assumption that the line breadth constant is 0.1 cm^{-1} for all of the lines. Recent evidence has indicated that the line breadth may vary from line to line. Such variations could cause the attenuation curve to rise much more rapidly with frequency than is shown in Fig. 3.

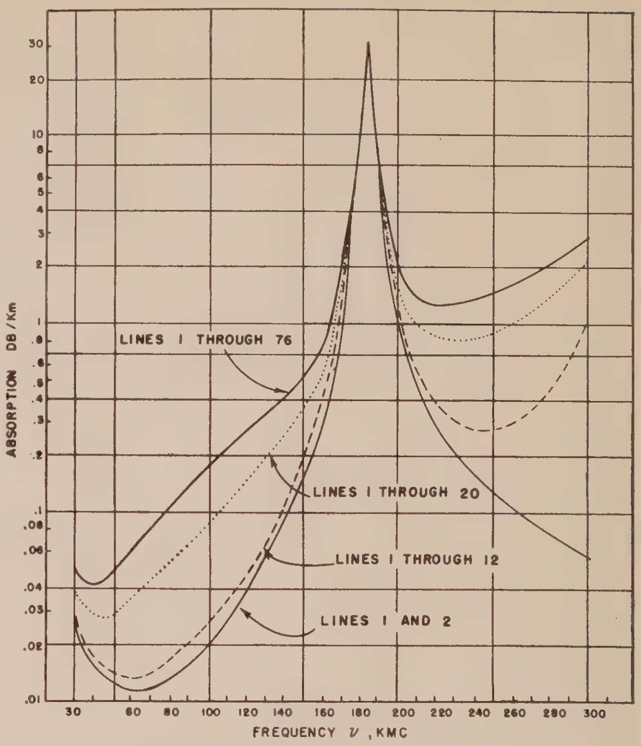

Fig. 3—Calculated water vapor absorption for 7.5 g/m^3 for $\Delta\nu/c=0.1$.

All of the water vapor loss measurements made prior to September 1958 could be approximately accounted for by the expediency of increasing the line breadth constant for the infrared residual lines from 0.1 to 0.27 cm^{-1}.

Recent measurements at The University of Texas, however, have uncovered several anomalies which have thrown out this simple panacea. These newer measurements are described in the following sections.

Measurements Around the 1.35-cm Line

In spite of the fact that the frequency of the 1.35-cm line has been known with precision for some time, quantitative measurements of the magnitude of its absorption through the actual atmosphere are very scarce. For this reason, data were recently taken by the Electrical Engineering Research Laboratory at a number of wavelengths in this region.[13]

These recent data are plotted in Fig. 4 together with the three points reported by Dicke, *et al.*[9] The curve is plotted on a linear basis for one gram of water vapor per cubic meter instead of for the standard atmosphere condition of 7.5 grams. Neither the Van Vleck-Weisskopf curve for the 0.1 cm^{-1} nor for the 0.27 cm^{-1} line breadth constant adequately represents the measured data even in the vicinity of the absorption line.

Measurements in the 2.5 to 3.0-mm Region

Water Vapor Losses

The University of Texas has recently completed a series of measurements in the wavelength region from 2.5 to 3.0 mm.[14] Sufficient data were taken to obtain the slope of the water vapor line at frequencies of 100, 104.75, 110, 113 and 117.5 kmc, and these five points are shown in Fig. 2. Two anomalies are seen from these data. In the first place, the level of the attenuation is approximately 50 per cent higher than would be indicated by the Van Vleck-Weisskopf equation even for a line breadth constant of 0.27 cm^{-1}. In the second place, the loss at 110 kmc is greater than the loss at the other four frequencies. Although no water vapor line has been predicted at 110 kmc, the increased attenuation at this frequency indicates that such a line may exist.

In addition to the five frequencies at which sufficient data were taken to obtain the water vapor slope, one or more soundings were made at 23 other frequencies in this region. The data were adjusted to the 7.5-grams-per-cubic-meter atmosphere by using a water vapor line slope obtained by interpolating between the values measured at the five frequencies. This may be done with some confidence since the correction applied was a function of the deviation from the standard atmosphere condition. The attenuation adjusted to the standard atmosphere is then shown in Fig. 5.

Oxygen Losses

From the shape of the smooth curve drawn through the higher frequency points, an oxygen absorption line may be fitted. It was found that a line with a resonant frequency of 118.75, a maximum attenuation of 1.7 db/km and a line breadth constant of 0.05 cm^{-1} would give the measured shape.

The line breadth constant at this frequency had been found by Anderson, *et al.*,[15] to be 0.12 cm^{-1} at one atmosphere by laboratory methods. These measurements were made at a temperature of 190° K. A temperature correction to 300° K may be made using the line breadth as inversely proportional to temperature as measured by Hill and Gordy,[16] but the corrected value is still considerably greater than that determined by the propagation measurements.

A similar discrepancy exists around the 5-mm lines. Artman and Gordon[17] determined a line breadth of 0.049 cm^{-1} from laboratory measurements on pure O_2 and O_2-N_2 mixtures. Propagation measurements by Bell Telephone Laboratories and The University of Texas have indicated that the line breadth constant should be nearer 0.02 cm^{-1}.[10,18]

Losses Due to Rare Gases

The data in the region from 100 to 106 kmc were found to be erratic with day-to-day variations which did not correlate with the water vapor density changes. It was therefore felt that these losses were due to some of the rarer gases in the atmosphere such as N_2O, NO_2, SO_2, and O_3, which have resonant frequencies in this general area. These irregular losses were about 0.2 db/km during the measurement period.

CHANGE IN ATTENUATION WITH PRESSURE

High elevation measurements have been made by The University of Texas at wavelengths of 8.6,[19] 4.3[20] and 2.15[11] mm. These data were taken over paths between mountain peaks in Colorado with elevations from 12,000 to 14,000 feet. Losses due to water vapor were measured at all three wavelengths and the loss due to oxygen was measured at 4.3 mm. The oxygen losses at 8.6 and 2.15 were too small to measure with accuracy. The results of these measurements are shown in Table I.

TABLE I

Wavelength (mm)	Attenuation in db/km	
	Water Vapor (1g/m³)	Oxygen
8.6	0.03	
4.3	0.10	0.22
2.15	0.12	

It is generally assumed that at the resonant frequency the loss for the same concentration of the absorbing gas will be the same regardless of the total pressure of the atmosphere. It is also assumed that the line breadth constant is proportional to the total pressure.

The losses for the higher altitude may be calculated from the Van Vleck-Weisskopf equation by adjusting the line breadth constant for the pressure change starting with line breadth constants at one atmosphere of 0.27 cm^{-1} for water vapor, and 0.02 cm^{-1} for oxygen. Losses calculated on this basis were found to agree reasonably well with the measurements.

In the light of recent anomalies at 1.35 cm and 2.6 mm, however, it would be expected that additional anomalies may be found at high altitudes for other wavelengths. The use of the Van Vleck-Weisskopf equation for higher altitudes should then be limited to the part of the spectrum in which the measurements were made.

DISCUSSION OF DEVIATION OF MEASURED AND PREDICTED ABSORPTION VALUES

In trying to fit the measured points with the Van Vleck-Weisskopf line broadening equation, we find that the use of a single line breadth constant is inadequate. The data may be approximately fitted by introducing a number of line strength and line width constants. In so doing, however, the equation loses much of its simplicity and utility. Some of the relationships that account for the anomalies will be discussed in this section.

Variation of Line Breadth Constant from Line to Line

Benedict and Kaplan[21] point out that there is considerable theoretical and experimental evidence that the line width for the various water vapor lines is different depending on the rotational states involved. With the imposing array of lines which influence millimeter absorption, the absorption-frequency curve could take on a wide variety of shapes. The general effect would be that of having a greater increase in absorption with frequency as the shorter millimeter wavelengths are approached. This has been the general trend in the measured water vapor loss since the ratio of the measured losses to those predicted by Van Vleck vary from three to ten as the frequency goes from 35 to 140 kmc.

Possibility of Unpredicted Lines

The measurements in the 100- to 118-kmc range indicated that a water vapor line occurs at 110 kmc. Although no line has been predicted at this frequency, it would not be surprising if one did occur because of the very complex nature of the water vapor transitions.

An alternate explanation of the water sensitive loss at 110 kmc is that an isotope of H_2O or another of the rarer gases in the atmosphere would vary in concentration in proportion to the water vapor density. There is, however, little theoretical justification of the increased attenuation on this basis.

The effect of some of the rarer gases was observed in the 100- to 106-kmc region where erratic losses of approximately 0.2 db/km were noted. These losses did not vary in proportion to the water vapor concentration, but changed inconsistently from day to day. This is the only region where these effects could be noted, although they might be expected at other frequencies to a lesser amount.

Nonlinearity of Water Vapor Absorption

Water vapor absorption curves as a function of water vapor concentration as measured by The University of Texas and by Bell Telephone Laboratories have shown a tendency to increase faster with water vapor concentration than at a straight line rate. The range of water vapor concentration and the variability of the result have made it difficult to determine the exact deviation from a straight line.

If such nonlinearity does exist, it must be due to the fact that H_2O-H_2O molecular collisions have a much greater effect on line broadening than do H_2O-Air collisions. Becker and Autler estimate a ratio of 5 in the cross section of the H_2O-H_2O collision as compared to the H_2O-Air collision.

Limitation on Van Vleck-Weisskopf Equation

As pointed out by Van Vleck,[2] an explanation of the deviation of theoretical and experimental determinations of atmospheric absorption could result from limitations of the Van Vleck-Weisskopf equation in the far wings. The validity of this equation when the line widths are in the same order of magnitude as the resonant frequency has been questioned.

On the high-frequency side of the absorption lines, the Van Vleck-Weisskopf equation predicts that the loss will approach a constant. This is known to break down in the infrared region, but the extent of its validity is difficult to predict.

The Van Vleck-Weisskopf equation is based entirely on the broadening of the absorption lines by collisions of the molecules. Other factors which affect line broadening include Doppler broadening, saturation broadening, and radiation broadening. Each of these effects has been discussed by Rogers.[22] Although these other broadening factors are generally considered to be negligible, the possibility of their making a significant contribution should not be overlooked.

CONCLUSIONS

Measurements of the absorption of microwaves by the atmosphere have indicated that theoretical predictions of the losses are not entirely satisfactory. Oxygen losses in the vicinity of the absorption lines may be explained satisfactorily by the proper choices of the line breadth constants. The line breadth constants are, however, lower than those predicted on the basis of nonpropagation-type laboratory measurements.

The measured water vapor losses are consistently higher than predicted. No single line breadth constant will satisfactorily explain the experimental data.

It is felt, therefore, that the extension of experimental absorption data to frequencies, pressures, or mixture ratios considerably different from those used in the measurement programs should be avoided.

APPENDIX

VAN VLECK-WEISSKOPF EQUATION

If a single spectral line, remote from all others, is considered, the attenuation in decibels per kilometer of an incoming electromagnetic wave is given by

$$\gamma = \frac{[10^6 \log_{10} e] 8\pi^2 N p \nu^2 |\mu_{JJ'}|^2 e^{-W_J/kT} S}{3ckTGP}$$

where

γ = absorption coefficient, in decibels per kilometer

c = speed of light $= 2.9979 \times 10^{10}$ cm per second

k = Boltzmann's constant $= 1.3802565 \times 10^{-16}$ erg per degree Kelvin

p = partial vapor pressure of the absorbing gas, in mm of Hg

P = total pressure of the atmosphere, in mm of Hg

T = temperature of the atmosphere, in degrees Kelvin

G = rotational partition function of the absorbing gas (dimensionless)

N = number of molecules per cubic centimeter in the atmosphere $= 9.66 \times 10^{18} \times P/T$

ν = frequency of the incoming electromagnetic wave, in cycles per second

W_J = the energy of the absorbent lower rotational state J, in cm^{-1}

$|\mu_{JJ'}|^2$ = square of the dipole moment matrix element associated with the absorbent rotational transition $J \rightarrow J'$, inclusive of the static dipole moment and weighting factors (dimensionless)

S = the modified structure factor

$$= \frac{\Delta\nu}{(\nu_{JJ'} - \nu)^2 + (\Delta\nu)^2} + \frac{\Delta\nu}{(\nu_{JJ'} + \nu)^2 + (\Delta\nu)^2}$$

where

$\Delta\nu$ = absorption line half-intensity half-width, in cycles per second

$\nu_{JJ'}$ = the center or resonant frequency of the absorbent rotational transition $J \rightarrow J'$, in cycles per second.

As used throughout this paper, the line breadth constant is taken as $\Delta\nu/c$ with the unit of cm^{-1}.

Interaction Impedance Measurements by Propagation Constant Perturbation*

P. R. McISAAC†, ASSOCIATE MEMBER, IRE, AND C. C. WANG‡, FELLOW, IRE

Summary—**The perturbation in the complex propagation constant of a lossy, nonreciprocal, periodic waveguide produced by the insertion of a rod, which may be cylindrical or periodic, parallel to the waveguide axis is developed. The application to the experimental determination of the interaction impedance and electromagnetic field distribution of waveguides is presented, together with the approximations which are applicable. The perturbation formulas for three particular classes of circuit—lossless, reciprocal, cylindrical circuits; lossy, nonreciprocal, cylindrical circuits; and lossy, nonreciprocal, periodic circuits—of interest for traveling wave tubes and other extended interaction microwave tubes, are derived and the limitations discussed. Explicit interaction impedance relations for these circuits in terms of the phase constant perturbation, caused by a cylindrical or periodic rod, are given.**

I. INTRODUCTION

PERTURBATION techniques have proved to be useful for determining experimentally the electromagnetic field distributions both in resonant microwave structures, such as klystron cavities, and propagating structures, such as slow wave circuits for traveling wave tubes. In particular, the determination of the interaction impedance $Z=E^2/2\beta^2S$ of traveling wave tube circuits is readily accomplished using perturbation measurements (S is the total power on the circuit, β is the propagation constant, and E is the peak longitudinal electric field strength at the position where the electron beam will be located). The techniques for using a resonated section of the circuit (resonated using shorting plates) and obtaining the interaction impedance from a measurement of the change in resonant frequency of the section caused by the insertion of a small dielectric or metallic bead are well known.[1,2] One formulation of the relationship between the perturbing bead parameters, the change in the resonant frequency, and the electromagnetic fields in the resonant section which has a close relation to the treatment presented here has been given by Casimir.[3] There have been many others as well.[4–7] Of course, the converse procedure of using the change in resonant frequency and Q of a standard cavity to investigate the dielectric and magnetic parameters of small samples of material introduced into the cavity is also well known.

For stability reasons, most traveling wave tube circuits are intentionally made somewhat lossy. These lossy circuits are not amenable to the resonant section technique because of their low Q and the resulting difficulty in measuring the resonant frequency accurately. In addition, there has been some interest in recent years in using ferrite loaded circuits to obtain nonreciprocal attenuation properties, and these circuits are not readily adapted to conventional resonant section perturbation techniques because of the nonreciprocity. Therefore, measurement techniques which are applicable to propagating circuits and use the perturbation of the propagation constant by a bead or rod to determine the electromagnetic field pattern and the interaction impedance are necessary. Of course, the propagation constant perturbation and the resonant frequency perturbation measurements are complementary and closely related. For example, measurements on a propagating circuit might be made by determining the change in applied frequency necessary to hold the propagation constant unchanged when a perturbing object is inserted. However, attention will be confined here to constant frequency measurements in which the propagation constant is perturbed.

Measurements of the interaction impedance of slow wave circuits using the technique of the perturbation of the propagation constant are, of course, not new.[2] Kino[8] has given a derivation of the propagation constant perturbation caused by a dielectric or metallic rod in a lossy, periodic, reciprocal system using normal mode techniques. Lagerstrom[9] has considered lossless, peri-

odic, reciprocal systems and analyzed in some detail the effects of perturbing rod size as well as periodic rods. The treatment here will be applicable to lossy, periodic, nonreciprocal structures and is based on a field theory approach which gives a direct derivation of an exact relationship and facilitates the evaluation of approximations convenient for measurements. The derivation is basically analogous to Casimir's[3] treatment of lossless resonant cavities, but is a generalization and adaptation applicable to lossy, periodic, nonreciprocal, propagating structures. Several related treatments are also of interest. Goubau[10] has discussed the perturbation of the input impedance of an electromagnetic system caused by the insertion of a test body, while Redfield[11] has considered the perturbation of the admittance matrix of an electrodynamic system. Auld[12] has developed a related perturbation theorem for the scattering matrix at a junction.

II. Derivation of Basic Equations

Consider a waveguide of arbitrary cross section which is periodic with period L in the direction of propagation z and which has a single frequency wave propagating in the z direction. It is assumed that only one of the possible modes of the structure is excited. By Floquet's theorem, the fields in the waveguide may be written as

$$\begin{aligned} \boldsymbol{E}_i(x, y, z, t) &= \boldsymbol{E}_0(x, y, z)e^{j\omega t-\Gamma_0 z} \\ &= \sum_n \boldsymbol{E}_{0n}(x, y)e^{j\omega t-(\Gamma_0+j2\pi n/L)z}, \end{aligned} \tag{1a}$$

$$\begin{aligned} \boldsymbol{H}_i(x, y, z, t) &= \boldsymbol{H}_0(x, y, z)e^{j\omega t-\Gamma_0 z} \\ &= \sum_n \boldsymbol{H}_{0n}(x, y)e^{j\omega t-(\Gamma_0+j2\pi n/L)z}, \end{aligned} \tag{1b}$$

where the propagation constant $\Gamma_0=\alpha_0+j\beta_0$ is complex for a lossy waveguide. Note that $\boldsymbol{E}_0$ and $\boldsymbol{H}_0$ are periodic in z with period L, while the space harmonic field amplitudes $\boldsymbol{E}_{0n}$ and $\boldsymbol{H}_{0n}$ are independent of z. If the waveguide is cylindrical rather than periodic, all the $\boldsymbol{E}_{0n}$ and $\boldsymbol{H}_{0n}$ for $n\neq 0$ are zero.

Now let a rod be inserted into the waveguide parallel to, but not necessarily coinciding with, the z axis. The "rod" may be either uniform in cross section, or be periodic in z with period L, *e.g.*, a series of beads spaced at intervals equal to L. Hereafter, the term "rod" will refer to either of these configurations unless explicitly stated to the contrary. The final fields after the insertion of the rod will be

$$\begin{aligned} \boldsymbol{E}_f(x, y, z, t) &= [\boldsymbol{E}_0(x, y, z) + \boldsymbol{E}_1(x, y, z)]e^{j\omega t-(\Gamma_0+\Gamma_1)z} \\ &= \sum_n [\boldsymbol{E}_{0n}(x, y) + \boldsymbol{E}_{1n}(x, y)]e^{j\omega t-(\Gamma_0+\Gamma_1+j2\pi n/L)z} \end{aligned} \tag{2a}$$

$$\begin{aligned} \boldsymbol{H}_f(x, y, z, t) &= [\boldsymbol{H}_0(x, y, z) + \boldsymbol{H}_1(x, y, z)]e^{j\omega t-(\Gamma_0+\Gamma_1)z} \\ &= \sum_n [\boldsymbol{H}_{0n}(x, y) + \boldsymbol{H}_{1n}(x, y)]e^{j\omega t-(\Gamma_0+\Gamma_1+j2\pi n/L)z}. \end{aligned} \tag{2b}$$

It is assumed that only a single mode of the perturbed system has been excited, with a propagation constant $\Gamma_0+\Gamma_1=\alpha_0+\alpha_1+j(\beta_0+\beta_1)$, and that this mode has a field distribution which is roughly similar to that of the original mode.

From Maxwell's curl equations,

$$\nabla \times \boldsymbol{E}_0 - \Gamma_0(\boldsymbol{k} \times \boldsymbol{E}_0) = -j\omega \boldsymbol{B}_0, \tag{3a}$$

$$\nabla \times \boldsymbol{H}_0 - \Gamma_0(\boldsymbol{k} \times \boldsymbol{H}_0) = j\omega \boldsymbol{D}_0, \tag{3b}$$

$$\begin{aligned} \nabla \times \boldsymbol{E}_1 - (\Gamma_0 + \Gamma_1)(\boldsymbol{k} + \boldsymbol{E}_1) - \Gamma_1(\boldsymbol{k} \times \boldsymbol{E}_0) \\ = -j\omega \boldsymbol{B}_1, \end{aligned} \tag{3c}$$

$$\nabla \times \boldsymbol{H}_1 - (\Gamma_0 + \Gamma_1)(\boldsymbol{k} \times \boldsymbol{H}_1) - \Gamma_1(\boldsymbol{k} \times \boldsymbol{H}_0) = j\omega \boldsymbol{D}_1, \tag{3d}$$

where $\boldsymbol{k}$ is a unit vector in the z direction. By multiplying (3c) and (3d), respectively, by $\boldsymbol{H}_0^*$ and $\boldsymbol{E}_0^*$ (* denotes complex conjugate), combining, and using a vector identity,

$$\begin{aligned} &\boldsymbol{E}_0^* \cdot \nabla \times \boldsymbol{H}_1 - \boldsymbol{H}_0^* \cdot \nabla \times \boldsymbol{E}_1 = -\nabla \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*) \\ &\quad - \boldsymbol{E}_1 \cdot \nabla \times \boldsymbol{H}_0^* + \boldsymbol{H}_1 \cdot \nabla \times \boldsymbol{E}_0^* \\ &= -\Gamma_1 \boldsymbol{k} \cdot (\boldsymbol{E}_0 \times \boldsymbol{H}_0^* + \boldsymbol{E}_0^* \times \boldsymbol{H}_0) - (\Gamma_0 + \Gamma_1)\boldsymbol{k} \\ &\quad \cdot (\boldsymbol{E}_1 \times \boldsymbol{H}_0^* + \boldsymbol{E}_0^* \times \boldsymbol{H}_1) + j\omega(\boldsymbol{E}_0^* \cdot \boldsymbol{D}_1 + \boldsymbol{H}_0^* \cdot \boldsymbol{B}_1). \end{aligned} \tag{4}$$

After multiplication by exp $(-2\alpha_0 z)$ and utilization of a vector identity, integration over one period of the waveguide, and the application of Gauss' theorem, there results

$$\begin{aligned} &\Gamma_1 \iiint_V \boldsymbol{k} \cdot (\boldsymbol{E}_0 \times \boldsymbol{H}_0^* + \boldsymbol{E}_0^* \times \boldsymbol{H}_0)e^{-2\alpha_0 z}dv \\ &\quad + \Gamma_1 \iiint_V \boldsymbol{k} \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*)e^{-2\alpha_0 z}dv \\ &= j\omega \iiint_V (\boldsymbol{E}_0^* \cdot \boldsymbol{D}_1 - \boldsymbol{D}_0^* \cdot \boldsymbol{E}_1 + \boldsymbol{H}_0^* \\ &\qquad \cdot \boldsymbol{B}_1 - \boldsymbol{B}_0^* \cdot \boldsymbol{H}_1)e^{-2\alpha_0 z}dv \\ &\quad + \iint_A \boldsymbol{n} \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*)e^{-2\alpha_0 z}da. \end{aligned} \tag{5}$$

Here V denotes a volume corresponding to one period of the waveguide, A denotes the surface area enclosing this volume, and $\boldsymbol{n}$ is a unit vector normal to this surface, directed outward. Any currents present in materials with finite conductivity are included in the electric displacement vectors $\boldsymbol{D}_0$ and $\boldsymbol{D}_1$ by having the imaginary part of the dielectric constant include the conductivity as well as the dielectric loss term.

[11] A. G. Redfield, "An electrodynamic perturbation theorem, with application to non-reciprocal systems," *J. Appl. Phys.*, vol. 25, pp. 1021–1024; August, 1954.

[12] B. Auld, "The synthesis of symmetrical waveguide circulators," IRE Trans. on Microwave Theory and Techniques, vol. MTT-7, pp. 238–246; April, 1959.

We note that $\boldsymbol{D}_0 = \hat{\epsilon}_i \cdot \hat{\boldsymbol{E}}_0$ and $\boldsymbol{B}_0 = \hat{\mu}_i \cdot \boldsymbol{H}_0$, where $\hat{\epsilon}_i$ and $\hat{\mu}_i$ are the dielectric constant and permeability of the material in the waveguide prior to the insertion of the perturbing rod. These, in general, will be functions of position within the waveguide and complex to account for losses. The circumflex indicates that these may be tensor quantities, as is, for example, the permeability of a ferrite material. Also, in all regions external to the perturbing rod, $\boldsymbol{D}_1 = \hat{\epsilon}_i \cdot \boldsymbol{E}_1$ and $\boldsymbol{B}_1 = \hat{\mu}_i \cdot \boldsymbol{H}_1$. Since it is assumed that the rod is inserted only into regions which were previously empty, (5) may be rewritten as

$$\begin{aligned}
\Gamma_1 \iiint_V & \boldsymbol{k} \cdot (\boldsymbol{E}_0 \times \boldsymbol{H}_0^* + \boldsymbol{E}_0^* \times \boldsymbol{H}_0) e^{-2\alpha_0 z} dv \\
& + \Gamma_1 \iiint_V \boldsymbol{k} \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*) e^{-2\alpha_0 z} dv \\
= j\omega & \iiint_{\delta V} (\epsilon_0 \boldsymbol{E}_0^* \cdot \boldsymbol{P} + \mu_0 \boldsymbol{H}_0^* \cdot \boldsymbol{M}) e^{-2\alpha_0 z} dv \\
& + j\omega \iiint_{V-\delta V} [\boldsymbol{E}_0^* \cdot (\hat{\epsilon}_i \boldsymbol{E}_1) - \boldsymbol{E}_1 \cdot (\hat{\epsilon}_i \cdot \boldsymbol{E}_0)^* + \boldsymbol{H}_0^* \\
& \qquad \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_1) - \boldsymbol{H}_1 \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_0)^*] e^{-2\alpha_0 z} dv \\
& + \iint_A \boldsymbol{n} \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*) e^{-2\alpha_0 z} da, \qquad (6)
\end{aligned}$$

where $\boldsymbol{P} = \boldsymbol{D}_1/\epsilon_0 - \boldsymbol{E}_1$ and $\boldsymbol{M} = \boldsymbol{B}_1/\mu_0 - \boldsymbol{H}_1$ are the polarization and magnetization of the rod. δV denotes the volume of one period of the rod and $V - \delta V$ denotes the volume of one period of the waveguide exclusive of the rod volume. Eq. (6) is an exact expression relating the change in the propagation constant to the fields and the rod parameters. The first integral on the left is recognized to be four times the time average power in the z direction of the original unperturbed circuit integrated over a length in the z direction equal to one period of the structure. Thus, the first term on the left can be put in the form,

$$\begin{aligned}
\Gamma_1 \iiint_V & \boldsymbol{k} \cdot (\boldsymbol{E}_0 \times \boldsymbol{H}_0^* + \boldsymbol{E}_0^* \times \boldsymbol{H}_0) e^{-2\alpha_0 z} dv \\
& = 4\Gamma_1 \int_z^{z+L} S_0(z) dz, \qquad (7)
\end{aligned}$$

where $S_0(z)$ represents the time average power in the z direction. $S_0(z)$ is, of course, real so that by taking the real and imaginary parts of (6), expressions for α_1 and β_1 can be obtained.

The integrals in (6) are taken over one complete period of the structure; this is precisely defined for the z direction, but is somewhat vague for the transverse directions. For structures with enclosing, perfectly conducting walls, it suffices to integrate over the volume enclosed by the walls. In this case, of course, all the fields external to the region enclosed by the walls are zero. For open boundary structures, *e.g.*, an unshielded helix, the fields exist out to infinity, and one must integrate out to infinity in the transverse directions. For structures with imperfectly conducting walls, the fields will again extend out to infinity in the transverse directions. Those fields external to the walls are clearly negligible when the waveguide walls are made of the usual metals. However, to cover all possible cases here, we will integrate out to infinity in the transverse directions, but we recognize that for many important cases the contribution from the fields external to the waveguide walls will be completely negligible. By integrating out to infinity, the surface integral of (6) may be simplified because the fields will go to zero at infinity for structures that propagate a mode carrying finite power in the z direction. Thus, in all cases there will be a contribution to the surface integral possible only over planes that are normal to the z axis.

Using this simplification, (6) may be written as

$$\begin{aligned}
4\Gamma_1 & \int_z^{z+L} S_0(z) dz \\
& + \Gamma_1 \iiint_V \boldsymbol{k} \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*) e^{-2\alpha_0 z} dv \\
= j\omega & \iiint_{\delta V} (\epsilon_0 \boldsymbol{E}_0^* \cdot \boldsymbol{P} + \mu_0 \boldsymbol{H}_0^* \cdot \boldsymbol{M}) e^{-2\alpha_0 z} dv \\
& + j\omega \iiint_{V-\delta V} [\boldsymbol{E}_0^* \cdot (\hat{\epsilon}_i \cdot \boldsymbol{E}_1) - \boldsymbol{E}_1 (\hat{\epsilon}_1 \cdot \boldsymbol{E}_0)^* + \boldsymbol{H}_0^* \\
& \qquad \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_1) - \boldsymbol{H}_1 \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_0)^*] e^{-2\alpha_0 z} dv \\
& - (1 - e^{-2\alpha_0 L}) e^{-2\alpha_0 z} \iint_{A_c} \boldsymbol{k} \\
& \qquad \cdot (E_0^* \times H_1 + E_1 \times H_0^*) da. \qquad (8)
\end{aligned}$$

Here A_c represents the waveguide cross section at $z = z$ or $z = z + L$ (the cross section at these two points is the same because of the periodicity). As noted above, A_c may extend out to infinity. It should be observed that the equality in (8) is independent of the value of z chosen.

III. APPLICATION TO INTERACTION IMPEDANCE MEASUREMENTS

Eq. (8) is the basic equation with which we will deal. As it stands, it is too cumbersome to be useful in practice, but in many cases of interest, approximations can be made which render it useful for the experimental measurement of the interaction impedance. In order to determine what approximations are valid and their implications, several special cases will be examined in some detail.

A. Lossless, Reciprocal, Cylindrical Waveguides

In this case $\alpha_0 = 0$, the dielectric constant and permeability are real scalars, and since only the fundamental space harmonic fields exist, each of the integrands in (8) has the same z dependence, exp $(-2\alpha_0 z)$, and the integration over z may be omitted. β_1 is found by adding (8) to its complex conjugate.

$$\beta_1 = \omega \frac{\iint_{\delta A} \left[\epsilon_0(\boldsymbol{E}_0^* \cdot \boldsymbol{P} + \boldsymbol{E}_0 \cdot \boldsymbol{P}^*) + \mu_0(\boldsymbol{H}_0^* \cdot \boldsymbol{M} + \boldsymbol{H}_0 \cdot \boldsymbol{M}^*)\right] da}{8S_0 + \iint_{A_c} \boldsymbol{k} \cdot (\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_0 \times \boldsymbol{H}_1^* + \boldsymbol{E}_1 \times \boldsymbol{H}_0^* + \boldsymbol{E}_1^* \times \boldsymbol{H}_0) da}. \tag{9}$$

δA denotes the cross section of the perturbing rod which is cylindrical.

It will be observed that, so far, no restrictions have been placed on the constancy of the power before and after the rod insertion. Naturally, β_1 is independent of the power level, but the individual integrals in (9) will vary with the power. For convenience, we will arbitrarily demand that the power level be kept constant throughout the measurements. That is,

$$S_0 = S_0 + S_1, \tag{10a}$$

$$S_1 = 0, \tag{10b}$$

where S_1 is the change in power,

$$S_1 = \frac{1}{4} \iint_{A_c} \boldsymbol{k} \cdot (E_0 \times H_1^* + E_0^* \times H_1 + E_1 \times H_0^* + E_1^* \times H_0 + E_1 \times H_1^* + E_1^* \times H_1) e^{-2\alpha_0 z} da. \tag{11}$$

Therefore,

$$\iint_{A_c} \boldsymbol{k} \cdot (\boldsymbol{E}_1 \times \boldsymbol{H}_1^* + \boldsymbol{E}_1^* \times \boldsymbol{H}_1) e^{-2\alpha_0 z} da = -\iint_{A_c} \boldsymbol{k} \cdot (\boldsymbol{E}_0 \times \boldsymbol{H}_1^* + \boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^* + \boldsymbol{E}_1^* \times \boldsymbol{H}_0) e^{-2\alpha_0 z} da. \tag{12}$$

It should be noted that (12) is general and holds for lossy, nonreciprocal, periodic waveguides as long as the power is held constant.

$$\beta_1 = \omega \frac{\iint_{\delta A} \left[\epsilon_0(\boldsymbol{E}_0^* \cdot \boldsymbol{P} + \boldsymbol{E}_0 \cdot \boldsymbol{P}^*) + \mu_0(\boldsymbol{H}_0^* \cdot \boldsymbol{M} + \boldsymbol{H}_0 \cdot \boldsymbol{M}^*)\right] da}{8S_0 - \iint_{A_c} \boldsymbol{k} \cdot (E_1 \times H_1^* + E_1^* \times H_1) da}. \tag{13}$$

This expression, which is exact, can be simplified by making two assumptions about the perturbing rod's parameters. 1) The rod's cross-sectional dimensions are small compared to the waveguide dimensions and the wavelength of the propagating wave. 2) The combined effect of the perturbing rod's dielectric constant, permeability, and cross-sectional area is such that, external to the rod, the perturbation of the fields is small. These assumptions imply that $|\beta_1| \ll \beta_0$.

As a consequence of these assumptions, we can relate the components of the polarization and magnetization in the rod to the components of the initial electric and magnetic fields at the rod location through the use of the effective electric and magnetic susceptibilities χ_e and χ_m of the rod material and the effective depolarizing and demagnetizing factors for the rod geometry. This use of geometrical factors implies that the rod cross section is at least elliptical. The polarization and magnetization components are given by $P_x = \chi_e E_{0x}/(1 + N_{ex}\chi_e)$, $M_x = \chi_m H_{0x}/(1 + N_{mx}\chi_m)$, etc., where N_{ex}, N_{mx} are the effective depolarizing and demagnetizing factors for fields in the x direction. With the assumptions above, N_e and N_m are given by the static values for an elliptic body. When several field components are simultaneously present, then each will separately produce a perturbation whose magnitude depends on the N value for the particular direction. The geometry of the rod may be adjusted to emphasize or minimize the perturbation caused by the field in any particular direction by controlling the N values.

The assumption that the fields in the rod are essentially uniform over the cross section means that the integrand in the numerator of (13) is independent of position in the rod. Finally, by assumption 2), it is seen that the second term in the denominator will be small compared to $4S_0$. Letting the subscript r refer to the value of the fields at the rod location, the change in the propagation constant is approximately given by

$$\beta_1 \cong \omega \delta A \frac{\left[\frac{\epsilon_0 \chi_e}{1 + N_e \chi_e} |E_0|_r^2 + \frac{\mu_0 \chi_m}{1 + N_m \chi_m} |H_0|_r^2\right]}{4S_0}, \tag{14}$$

which is the customary expression.

It has also been tacitly assumed that the rod itself is lossless. If the rod were lossy, then one or both of χ_e, χ_m would be complex and (14) would change slightly. Also, α_1 could be written down by subtracting (8) from its complex conjugate. For cases where the fields are not uniform over the rod cross section so that using the static values of N_e and N_m is not justified, correction factors may be obtained by examining the integral in the numerator of (9) for particular cases (Lagerstrom[9] has discussed correction factors in some detail).

Eq. (14) indicates that, by using dielectric rods for which $\chi_m = 0$, or metallic rods so shaped as to emphasize the effective χ_e relative to the effective χ_m, the interaction impedance can be obtained by measuring β_0, β_1, and the rod parameters.

$$Z = \frac{|E_0|_r^2}{2\beta_0^2 S_0} \cong \frac{2\beta_1}{\omega\beta_0^2 \delta A \dfrac{\epsilon_0 \chi_e}{1 + N_e \chi_e}}. \tag{15}$$

Eq. (15) also holds for lossless, reciprocal, periodic waveguides if the rod is cylindrical and inserted at a location where only one of the space harmonic fields has an appreciable magnitude. In this case, the impedance is that of the particular space harmonic, and E_0 should be replaced by E_{0n} in (15).

B. Lossy, Nonreciprocal, Cylindrical Waveguides

Again, since only the fundamental space harmonic can exist, all of the integrands of (8) have the same z dependence so that integration over z may be omitted. Eq. (8) now reduces to

$$\begin{aligned} 4\Gamma_1 S_0(z) &+ \Gamma_1 \iint_{A_c} \boldsymbol{k}\cdot(\boldsymbol{E}_0^* \times \boldsymbol{H}_1 + \boldsymbol{E}_1 \times \boldsymbol{H}_0^*) e^{-2\alpha_0 z} da \\ &= j\omega \iint_{\delta A} (\epsilon_0 \boldsymbol{E}_0^* \cdot \boldsymbol{P} + \mu_0 \boldsymbol{H}_0^* \cdot \boldsymbol{M}) e^{-2\alpha_0 z} da \\ &\quad + j\omega \iint_{Ac-\delta A} [\boldsymbol{E}_0^* \cdot (\hat{\epsilon}_i \cdot \boldsymbol{E}_1) - \boldsymbol{E}_1 \cdot (\hat{\epsilon}_i \cdot \boldsymbol{E}_0)^* \\ &\qquad + \boldsymbol{H}_0^* \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_1) - \boldsymbol{H}_1 \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_0)^*] e^{-2\alpha_0 z} da. \end{aligned} \tag{16}$$

Inasmuch as the most important sources of nonreciprocal effects at microwave frequencies are ferrite materials, $\hat{\mu}_i$ will be taken as a tensor but $\hat{\epsilon}_i$ will be regarded as a scalar. Therefore, in the last integral of (16),

$$\boldsymbol{E}_0^* \cdot (\hat{\epsilon}_i \cdot \boldsymbol{E}_1) - \boldsymbol{E}_1 \cdot (\hat{\epsilon}_i \cdot \boldsymbol{E}_0)^* = \boldsymbol{E}_0^* \cdot \boldsymbol{E}_1 \, (\epsilon_i - \epsilon_i^*). \tag{17}$$

$\boldsymbol{E}_0^* \cdot \boldsymbol{E}_1$ will be real in the lossless case and not far different for the usual range of traveling wave tube attenuation. $(\epsilon_i - \epsilon_i^*)$ will be nonzero only in regions where there is lossy dielectric material or material with finite conductivity. Since $(\epsilon_i - \epsilon_i^*)$ is pure imaginary, (17) will be nearly pure imaginary. Therefore, its contribution to β_1 will be negligible, although the contribution to α_1 may be significant.

The situation regarding the magnetic field terms of the last integral in (16) is somewhat more complex. In general, there can be a contribution to β_1 from these terms even in the lossless case because of the off-diagonal elements of the permeability tensor. Thus, it is not clear in the general case what the relative magnitude of the contribution to β_1 from these terms will be. However, there is one important class of ferrite loaded waveguide structures about which more may be said. If the magnetic fields within the ferrite are circularly polarized in a plane perpendicular to the direction of the applied dc magnetic field, then the effective permeability tensor becomes diagonal.[13] If we assume that the perturbing rod is so located that the perturbed field is also circularly polarized in the ferrite, then

$$\boldsymbol{H}_0^* \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_1) - \boldsymbol{H}_1 \cdot (\hat{\mu}_i \cdot \boldsymbol{H}_0)^* = \boldsymbol{H}_0^* \cdot \boldsymbol{H}_1 (\mu_{cp} - \mu_{cp}^*), \tag{18}$$

where μ_{cp} represents the effective permeability in this case. This is the same form that occurred in (17) so that the remarks made there apply here as well. It is reasonable to assume that, in the more practical cases where the fields are not exactly circularly polarized but are nearly so in the ferrite, the contribution to β_1 of the term in (18) will still be negligible. This case, where the ferrite is located in a circularly polarized microwave field, is the one of most practical importance and most widespread use in traveling wave tubes.

In the more general situation of arbitrary polarization of the fields in the ferrite, the contribution to β_1 of the tensor permeability terms will be small if the perturbation is such that the change in the field energy stored within the ferrite associated with the off-diagonal permeability elements is small compared to the total change in field energy stored in the whole structure.

Assuming, then, that the above discussion is applicable, and introducing the two assumptions made in Section III, *A*,

$$\beta_1 \cong \frac{\omega\delta A e^{-2\alpha_0 z}}{4S_0(z)} \left\{ \frac{\epsilon_0}{2} \left[\left(\frac{\chi_e}{1 + N_e\chi_e} \right) + \left(\frac{\chi_e}{1 + N_e\chi_e} \right)^* \right] |E_0|_r^2 + \frac{\mu_0}{2} \left[\left(\frac{\chi_m}{1 + N_m\chi_m} \right) + \left(\frac{\chi_m}{1 + N_m\chi_m} \right)^* \right] |H_0|_r^2 \right\}, \tag{19a}$$

$$\begin{aligned} \alpha_1 \cong \frac{\omega\delta A e^{-2\alpha_0 z}}{4S_0(z)} &\left\{ \frac{\epsilon_0}{2} \left[\left(\frac{\chi_e}{1 + N_e\chi_e} \right) - \left(\frac{\chi_e}{1 + N_e\chi_e} \right)^* \right] |E_0|_r^2 + \frac{\mu_0}{2} \left[\left(\frac{\chi_m}{1 + N_m\chi_m} \right) - \left(\frac{\chi_m}{1 + N_m\chi_m} \right)^* \right] |H_0|_r^2 \right\} \\ &+ \frac{j\omega e^{-2\alpha_0 z}}{8S_0(z)} \iint_{A_c-\delta A} [(\epsilon_i - \epsilon_i^*)(\boldsymbol{E}_0^* \cdot \boldsymbol{E}_1 + \boldsymbol{E}_0 \cdot \boldsymbol{E}_1^*) + (\mu_{cp} - \mu_{cp}^*)(\boldsymbol{H}_0^* \cdot \boldsymbol{H}_1 + \boldsymbol{H}_0 \cdot \boldsymbol{H}_1^*)] da. \end{aligned} \tag{19b}$$

The expression for β_1 is in a form similar to (14) so that the remarks made there about the application to interaction impedance measurements apply here as well.

---

[13] D. Polder, "On the theory of ferromagnetic resonance," *Phil. Mag.*, vol. 40, pp. 99–115; January, 1949.

$$Z \cong \frac{4\beta_1}{\omega\beta_0{}^2\delta A\epsilon_0\left[\left(\dfrac{\chi_e}{1+N_e\chi_e}\right)+\left(\dfrac{\chi_e}{1+N_e\chi_e}\right)^*\right]}. \qquad (20)$$

The expression for α_1 reveals several interesting points. Under certain circumstances, a lossy rod may be used to make interaction impedance measurements by noting the change in attenuation of the structure when the rod is inserted. For this to be possible, the effective value of

$$\left(\frac{\chi_e}{1+N_e\chi_e}\right)-\left(\frac{\chi_e}{1+N_e\chi_e}\right)^*$$

relative to

$$\left(\frac{\chi_m}{1+N_m\chi_m}\right)-\left(\frac{\chi_m}{1+N_m\chi_m}\right)^*$$

must be large and the structure must either be originally low-loss and reciprocal, or the rod geometry and placement be such that the contribution to α_1 from the last integral of (19b) be negligible. Under these conditions,

$$Z \cong \frac{4\alpha_1}{j\omega\delta A\beta_0{}^2\epsilon_0\left[\left(\dfrac{\chi_e}{1+N_e\chi_e}\right)-\left(\dfrac{\chi_e}{1+N_e\chi_e}\right)^*\right]}. \qquad (21)$$

α_1 may be either positive or negative in general, depending on the field distribution relative to the lossy regions before and after inserting the rod. For example, if a lossless, high dielectric constant rod is inserted along the center of a waveguide with lossy walls, then α_1 will be negative because the rod causes an increased percentage of the total field energy to be concentrated in the lossless region. If this same rod were inserted along one of the waveguide walls, then α_1 might be positive since the percentage of the total field energy in the lossy region might increase.

C. Lossy, Nonreciprocal, Periodic Waveguides

For periodic structures it is necessary to retain the integration in z over a complete period of the waveguide since $\boldsymbol{E}_0$, $\boldsymbol{E}_1$, $\boldsymbol{H}_0$, $\boldsymbol{H}_1$, etc., are periodic functions of z. $S_0(z)$ will no longer vary as $\exp(-2\alpha_0 z)$ although it is still true that $S_0(z+L)$ differs from $S_0(z)$ by $\exp(-2\alpha_0 L)$. The z dependence of $S_0(z)$ will depend on the distribution of the lossy material in the waveguide. The discussion in Section III, *B* relative to the contribution of the dielectric loss terms and the tensor permeability to β_1 and α_1 applies to the periodic structure as well. Therefore, utilizing this and the assumptions made in Section III, *A*, (8) may be reduced to the following pair of equations for β_1 and α_1,

$$\beta_1 \cong \frac{\omega\delta A\displaystyle\int_z^{z+L}\left\{\frac{\epsilon_0}{2}\left[\left(\frac{\chi_e}{1+N_e\chi_e}\right)+\left(\frac{\chi_e}{1+N_e\chi_e}\right)^*\right]\boldsymbol{E}_0\cdot\boldsymbol{E}_0{}^*+\frac{\mu_0}{2}\left[\left(\frac{\chi_m}{1+N_m\chi_m}\right)+\left(\frac{\chi_m}{1+N_m\chi_m}\right)^*\right]\boldsymbol{H}_0\cdot\boldsymbol{H}_0{}^*\right\}e^{-2\alpha_0 z}dz}{4\displaystyle\int_z^{z+L}S_0(z)dz}, \qquad (22a)$$

$$\alpha_1 \cong \frac{j\omega\delta A\displaystyle\int_z^{z+L}\left\{\frac{\epsilon_0}{2}\left[\left(\frac{\chi_e}{1+N_e\chi_e}\right)-\left(\frac{\chi_e}{1+N_e\chi_e}\right)^*\right]\boldsymbol{E}_0\cdot\boldsymbol{E}_0{}^*+\frac{\mu_0}{2}\left[\left(\frac{\chi_m}{1+N_m\chi_m}\right)-\left(\frac{\chi_m}{1+N_m\chi_m}\right)^*\right]\boldsymbol{H}_0\cdot\boldsymbol{H}_0{}^*\right\}e^{-2\alpha_0 z}dz}{4\displaystyle\int_z^{z+L}S_0(z)dz}$$

$$+\frac{j\omega\displaystyle\int_z^{z+L}\iint_{A_c-\delta A}\left[(\epsilon_i-\epsilon_i{}^*)(\boldsymbol{E}_0\cdot\boldsymbol{E}_1^*+\boldsymbol{E}_1\cdot\boldsymbol{E}_0^*)+(\mu_{cp}-\mu_{cp}{}^*)(\boldsymbol{H}_0\cdot\boldsymbol{H}_1{}^*+\boldsymbol{H}_1\cdot\boldsymbol{H}_0{}^*)\right]e^{-2\alpha_0 z}da\,dz}{8\displaystyle\int_z^{z+L}S_0(z)dz}. \qquad (22b)$$

Each of the fields $\boldsymbol{E}_0$, $\boldsymbol{H}_0$, is made up of an infinite set of space harmonics. Because of the attenuation factor, $\exp(-2\alpha_0 z)$, the space harmonic fields are not orthogonal over the interval L so that cross-product terms of the space harmonics will appear in the integrals if $\boldsymbol{E}_0$ and $\boldsymbol{H}_0$ are replaced by $\boldsymbol{E}_{0n}\exp(-j2\pi nz/L)$ and $\boldsymbol{H}_{0n}\exp(-j2\pi nz/L)$, respectively, Therefore, the propagation constant perturbation β_1 will be, in general, a measure of an averaged field in the rod.

If only one space harmonic field has an appreciable amplitude at the rod location, then a cylindrical rod that perturbs primarily the electric field

$$\frac{\chi_e}{1+N_e\chi_e} \gg \frac{\chi_m}{1+N_m\chi_m}$$

may be used. This leads to

$$\beta_1 \cong \omega\delta A \frac{(1 - e^{-2\alpha_0 L})e^{-2\alpha_0 z}}{8\alpha_0 \int_z^{z+L} S_0(z)dz} \frac{\epsilon_0}{2} \cdot \left[\left(\frac{\chi_e}{1 + N_e\chi_e}\right) + \left(\frac{\chi_e}{1 + N_e\chi_e}\right)^*\right] \left| E_{0n} \right|_r^2. \tag{23}$$

It is easily seen that if α_0 approaches zero, (23) approaches (14) (with $\chi_m = 0$). If only a single space harmonic field is assumed to be present everywhere in the structure, then (23) approaches (19a) (with $\chi_m = 0$).

In some periodic circuits, $S_0(z)$ will still vary as $\exp(-2\alpha_0 z)$ so that (23) will simplify to (19a) in these cases. This is true, for example, for a helix inside a glass envelope with the lossy material distributed uniformly around the circumference. It would not be precisely true for a helix supported by lossy rods, but the discrepancy is probably not large. However, for the normal range of traveling wave tube attentuation, $\alpha_0 L$ will be small enough that

$$\frac{1 - e^{-2\alpha_0 L}}{2\alpha_0} \cong L \tag{24}$$

to a good approximation. Then (23) becomes

$$\beta_1 \cong \frac{\omega\delta A}{4} \left\{ \frac{e^{-2\alpha_0 z}}{\frac{1}{L}\int_z^{z+L} S_0(z)dz} \right\} \frac{\epsilon_0}{2} \cdot \left[\left(\frac{\chi_e}{1 + N_e\chi_e}\right) + \left(\frac{\chi_e}{1 + N_e\chi_e}\right)^*\right] \left| E_{0n} \right|_r^2. \tag{25}$$

This relates β_1 to the average power in one period of the structure. For lossy, periodic circuits, the quantity

$$\frac{1}{Le^{-\alpha_0 2}} \int_z^{z+L} S_0(z)dz/Le^{-2\alpha_0 z}$$

is the proper average value of power to insert into the interaction impedance formula, so that

$$Z_n \cong \frac{4\beta_1}{\omega\delta A\beta_n^2\epsilon_0 \left[\left(\frac{\chi_e}{1 + N_e\chi_e}\right) + \left(\frac{\chi_e}{1 + N_e\chi_e}\right)^*\right]}, \tag{26}$$

where Z_n is the interaction impedance of the nth space harmonic, recalling that only the nth space harmonic has an appreciable amplitude at the rod location, and $\beta_n = \beta_0 + 2\pi n/L$. Thus, a cylindrical rod is an adequate perturbation for a lossy glass enclosed helix as well as a lossy rod supported helix if the measurements are made on the helix axis where only the fundamental space harmonic field exists.

In regions where several space harmonics have appreciable amplitudes, a periodic array of beads may be used to determine Z_n. It will probably be necessary to use beads whose geometry is such as to cause an anisotropic perturbation in order to determine the field along a particular direction of interest. One effective arrangement is to use an array of needle shaped beads. For large length-to-diameter ratios, these will cause a perturbation when there is a component of field parallel to the long dimension but relatively little perturbation for components perpendicular to this direction. If the bead length as well as the cross section is small compared to a wavelength, then the field inside each bead is uniform and (22a) becomes

$$\beta_1 \cong \frac{\omega\delta V_b e^{-2\alpha_0 z'} \frac{\epsilon_0}{2}\left[\left(\frac{\chi_e}{1 + N_e\chi_e}\right) + \left(\frac{\chi_e}{1 + N_e\chi_e}\right)^*\right](\boldsymbol{E}_0 \cdot \boldsymbol{E}_0^*)_{z'}}{4\int_z^{z+L} S_0(z)dz}, \tag{27}$$

where z' denotes the position of the bead in the period of the structure under consideration. δV_b is the volume of one bead. $(\boldsymbol{E}_0^* \cdot \boldsymbol{E}_0)_{z'}$ may be written as

$$(\boldsymbol{E}_0 \cdot \boldsymbol{E}_0^*)_{z'} = \sum_n \sum_m \boldsymbol{E}_{0n} \cdot \boldsymbol{E}_{0m}^* e^{-j2\pi(n-m)z'/L} \tag{28}$$

which displays the periodic nature of this term. If β_1 is measured as a function of bead position, z', as the periodic array of beads is moved through one complete period of the structure, then Z_n can be determined. The plot of β_1 vs z' is seen from (27) and (28) to be given by a product of an exponential function $\exp(-2\alpha_0 z')$ and a periodic function $(\boldsymbol{E}_0 \cdot \boldsymbol{E}_0^*)_{z'}$. After extracting the exponential portion, the remaining periodic curve can be Fourier analyzed to determine the amplitudes of the space harmonic fields. From this, of course, the interaction impedance can be calculated.

IV. CONCLUSIONS

General relations for the perturbation of the real and imaginary parts of the propagation constant of lossy, nonreciprocal, periodic waveguides by a perturbing rod placed parallel to the axis have been developed. The rod may be either cylindrical or periodic, and lossless or lossy. Approximate formulas valid when the perturbation is small are readily obtained if the rod cross section is small compared to the wavelength so that the fields may be considered uniform, or nearly so, inside the rod.

The application of the propagation constant perturbation formulas to the measurement of the interaction impedance of propagating structures can be made, and one can use the perturbation of the phase constant by rods to determine the interaction impedance under fairly general conditions. These include lossy circuits where the attenuation constant is in the usual range for traveling wave tube circuits, and nonreciprocal circuits if the magnetic fields in the ferrite material are primarily circularly polarized. In fact, more general field distributions in the ferrite can be tolerated if the rod perturbation is such that the change in field energy in the ferrite is small relative to the total change in field energy stored in the whole structure. Periodic circuits are also included, and the space harmonic interaction impedance can be determined for these by using a periodic rod and Fourier analyzing the resulting curve of the phase constant vs rod position.

The perturbation of the attenuation constant of a waveguide by a lossy rod can also be used to measure the interaction impedance. The requirements in this case are that the structure be fairly low loss and reciprocal, or at least that the rod geometry and placement be such that the perturbation of the fields in the structure's lossy and nonreciprocal regions be small.

Attention has been directed here toward the use of propagation constant perturbation techniques to determine the interaction impedance of microwave tube circuits such as traveling wave tube or extended interaction klystron circuits. A closely related measurement is the exploration of electromagnetic field distributions in propagating circuits. Since with the proper conditions of small perturbation, etc., the change in the propagation constant is directly proportional to the ratio of the square of the fields divided by the power, the rod may be used to determine the field patterns. A dielectric rod, for example, whose geometry is such as to cause an anisotropic perturbation, may be used to obtain the relative magnitude and direction of the electric fields within the structure. This data, together with data taken using a metallic rod which will perturb both the electric and magnetic fields in general, can be used to deduce the magnetic field distribution. Of course, for a periodic circuit, the exploratory rods must also be periodic to take account of the space harmonic fields and a periodic array of properly shaped beads to give an anisotropic perturbation is useful.

And, of course, the perturbation technique is of great utility for investigating material parameters by using a standard structure whose electromagnetic field distribution is known and perturbing it by introducing the sample of material to be measured. The perturbation formulas developed above are readily applied to measurements of this type. In fact, this type of measurement is very useful in determining the rod parameters for rods to be used in the interaction impedance measurements discussed above at frequencies close to the measurement frequency. This permits the determination of the interaction impedance using purely experimental data for the rod's susceptibility, depolarizing factors, and volume.

Taylor-Cauchy Transforms for Analysis of a Class of Nonlinear Systems*

Y. H. KU†, SENIOR MEMBER, IRE, A. A. WOLF‡, MEMBER, IRE, AND J. H. DIETZ†, MEMBER, IRE

Summary—**This paper presents a new transform calculus for analyzing a certain class of nonlinear systems. The method, which can be justified rigorously by the partition theory,[1-3] essentially transforms a nonlinear differential equation having certain conditions imposed on its linear, nonlinear, and driving terms into an algebraic equation. The latter is easily solved recursively owing to its symmetry and convolution properties.**

The transform pair is based on a combination of the Cauchy integral theorem and Taylor's series in complex form. To illustrate the method a number of examples are solved and a table of transforms is included.

Because the results of this transform technique are the same as those given by the partition method under certain circumstances, the two are compared. It is then seen that the solution can be obtained uniquely and exactly.

The Taylor-Cauchy transform method can be compared with the Laurent-Cauchy transform method, given in a companion paper,[4] for the solution of linear systems described by differential-difference and sum equations.

I. INTRODUCTION

THIS paper introduces a transform calculus for analyzing a certain class of nonlinear systems both uniquely and exactly. In brief, the method consists of suitably transforming a nonlinear differential equation, which describes a given physical system, into a corresponding algebraic equation of the recurrent-convolution type. The latter equation is always capable of being solved recursively. In some instances, the recursion equation is solvable in closed form. In either case, the result is inverted or found in the table of Taylor-Cauchy transforms to give back the time function representing the response of the nonlinear network or system under analysis. On the one hand, when the solution of the transform equation is given in open form, the time function takes the form of Taylor's series. On the other hand, when the transform equation is solvable in closed form, its singularities can be found[1,5] and, as a consequence, the behavior of the system for large t is easily determined. When, in addition, the singularities turn out to be poles, the solution or response can be given in closed form.

The method of analysis presented here is applicable to a broad class of physical systems. The conditions specifying this class are explicitly stated in terms of the linear and nonlinear terms and of the driving forces[1-3] of an ordinary nonlinear differential equation such as

$$Z(D)\cdot x(t) + \phi(x, \dot{x}, \cdots) = g(t) \tag{1}$$

where $Z(D)$ is a linear differential operator defined as

$$Z(D) = \sum_{n=0}^{N_1} \alpha_n D^n \tag{2}$$

in which the α's are constants required to satisfy the condition that

$$y(t) = 0(e^{\tau_1 t}) \tag{3}$$

such that

$$y(t) = \frac{1}{2\pi j}\int_{Br} \frac{e^{st}}{Z(s)}\,ds \tag{4}$$

and

t is a real time variable,
s is a complex-frequency variable,
τ_1 is a constant specifying the type of $y(t)$,
$y(t)$ is the impulsive response of the linear part of (1),
Br denotes the proper Wagner-Bromwich contour in the s-plane,
$\phi(x, \dot{x}, \cdots)$ is a nonlinear function of the response and its derivatives, as the case may be, and is required to satisfy a modified Lipschitz condition discussed below,
$g(t)$ denotes the forcing function required to satisfy a condition like (3).

II. RESTRICTIONS ON SYSTEM

It was shown by Wolf[1-3] that under certain broad conditions the differential equation (1) represented a physical system so that the solution, $x(t)$, is governed by functions of exponential type. These conditions which

hold for the partition method also hold for the Taylor-Cauchy transforms. They are listed below for reference:

1) The linear operator $Z(D)$ has an impulsive response $y(t)$ of exponential type and order one.
2) The forcing function $g(t)$ is a function of exponential type and order one.
3) The nonlinear function $\phi(x, \dot{x}, \cdots)$ is single-valued and continuous and satisfies the following condition:

   Given a pair of positive constants M and a and two continuous functions $u(t)$ and $v(t)$ which are asymptotically like e^{-at}, then ϕ must satisfy the condition that

   $$|\phi[v(t)] - \phi[u(t)]| < Me^{-at}|v(t) - u(t)|$$

   for all $t \geq 0$.

In Wolf,[2] it is shown that the polynomial satisfies restriction 3) under certain conditions. Some transcendents[6] whose inverse functions possess algebraic derivatives can also be made to satisfy restriction 3). In this paper transforms are developed for the case in which ϕ is a polynomial nonlinearity such as

$$\phi(x) = \sum_{n=2}^{N_2} \beta_n x^n. \tag{5}$$

It is noted that any power-function combination of x and its derivatives is also admitted[3] in this method.

Eq. (1) as restricted possesses a unique solution which is an analytic function of t. Polynomials composed of the solution and its derivatives are also analytic functions. Hence, if terms are transposed from the left to the right member of (1), the new right member is an analytic function and may be written as a Taylor series.

In the partition method, from which the Taylor-Cauchy transform method is developed, the nonlinear terms in (1) are transposed. The combination of the forcing function, $g(t)$, and these transposed terms defines the *auxiliary forcing function*, $f(t)$, which is expressed as a Taylor series, the coefficients of which must be solved for. This is accomplished by convolving the series with the impulsive response of the linear terms in the left member to obtain an expression for $x(t)$ in terms of the coefficients of the series. This expression for $x(t)$ is substituted in the defining equation for the auxiliary forcing function to yield the coefficients.

Some or all of the linear terms except the term containing the *highest derivative* may also be transposed and included in the auxiliary forcing function. The auxiliary forcing function thus defined is, of course, a different function from that obtained when only the nonlinear terms are transposed. No matter how terms containing $x(t)$ and its derivatives (except the highest derivative) are transposed from the left to the right member of (1), the unique solution, $x(t)$, is obtained. Taylor-Cauchy transform methods yield the same solution in a more direct manner.

III. Description of the Method

Eq. (1) can be transformed into (6) below by the Taylor-Cauchy transformation, namely,

$$\mathfrak{J}_c[Z(D)\cdot x(t)] + \mathfrak{J}_c[\phi(x, x, \cdots)] = \mathfrak{J}_c[g(t)] \tag{6}$$

where $\mathfrak{J}_c$, the direct transform, is defined by

$$\mathfrak{J}_c[F(\lambda)] = \frac{1}{2\pi j}\int_C \frac{F(\lambda)}{\lambda^{n+1}}\,d\lambda, \qquad n = 0, 1, 2, \cdots \tag{7}$$

in which λ is a complex time variable[5] which replaces the real variable t in this transform method, and $F(\lambda)$ is any of the quantities inside the brackets in which t is replaced by λ and x is replaced by W. Thus

$$\begin{aligned} F_1(\lambda) &= Z(D)\cdot W(\lambda) \\ F_2(\lambda) &= \phi(W, \dot{W}, \cdots) \\ F_3(\lambda) &= G(\lambda) \\ D &= \frac{d}{d\lambda} \\ W &= W(\lambda) \\ \dot{W} &= \frac{dW(\lambda)}{d\lambda}. \end{aligned} \tag{8}$$

C denotes a closed contour in the λ-plane enclosing the singularities of $F(\lambda)$, and n is a discrete variable taking on discrete values $0, 1, 2, \cdots$.

It is noted that (6) is written as the sum of the transforms of the parts of (1), rather than as the transform of the sum of the parts of (1). In addition, the operation $\mathfrak{J}_c$ is commutative with a constant. That is to say,

$$\mathfrak{J}_c[aF(\lambda)] = a\mathfrak{J}_c[F(\lambda)]. \tag{9}$$

The additivity and commutivity properties of $\mathfrak{J}_c$ are often referred to in engineering literature as the linearity property of the transform. These properties follow immediately from the definition of the transform given in (7).

After performing the operations indicated in (6), one obtains a recurrence relation in a new function w_n, where $w_{n,k}$ is the $\mathfrak{J}_c$-transform mate of $W^{(k)}(\lambda)$, in which n is the discrete variable in the real positive n-half-line corresponding to the complex variable λ in the λ-plane, and k is the order of the system under analysis. This new equation is solved for w_n and by means of the inverse transform, $\mathfrak{J}_c^{-1}$, the response function, $W^{(k)}(\lambda)$, is recovered. This is the kth derivative of the desired solution. The inverse transform is given by

$$\mathfrak{J}_c^{-1}[w_n] = \sum_{n=0}^{\infty} w_n\lambda^n = W^{(k)}(\lambda). \tag{10}$$

---

[6] A. A. Wolf, "Analysis of Transcendental Nonlinear Systems," presented at the Summer General Meeting of AIEE, Buffalo, N. Y., paper 58-995; June 25, 1958.

Formally, then, applying (7) to (1) and noting (8) and (9), one sees that (6) becomes

$$\frac{1}{2\pi j}\int_C \frac{F_1(\lambda)}{\lambda^{n+1}}\,d\lambda + \frac{1}{2\pi j}\int_C \frac{F_2(\lambda)}{\lambda^{n+1}}\,d\lambda = \frac{1}{2\pi j}\int_C \frac{F_3(\lambda)}{\lambda^{n+1}}\,d\lambda \tag{11}$$

whereupon utilizing (2) and (5) leads to

$$\frac{1}{2\pi j}\int_C \frac{F_1(\lambda)}{\lambda^{n+1}}\,d\lambda = \frac{1}{2\pi j}\int_C \sum_{k=0}^{N_1} \alpha_k W^{(k)}(\lambda)\,\frac{d\lambda}{\lambda^{n+1}} \tag{12}$$

$$\frac{1}{2\pi j}\int_C \frac{F_2(\lambda)}{\lambda^{n+1}}\,d\lambda = \frac{1}{2\pi j}\int_C \sum_{k=2}^{N_2} \beta_k W^{k}(\lambda)\,\frac{d\lambda}{\lambda^{n+1}} \tag{13}$$

and

$$\frac{1}{2\pi j}\int_C \frac{F_3(\lambda)}{\lambda^{n+1}}\,d\lambda = \frac{1}{2\pi j}\int_C \frac{g(\lambda)}{\lambda^{n+1}}\,d\lambda. \tag{14}$$

IV. The Taylor-Cauchy Transform: Its Properties and Derivation

The Taylor-Cauchy transform is defined by the following pair of equations:

$$W^{(k)}(\lambda) = \sum_{n=0}^{\infty} w_{n,k}\lambda^n \tag{15}$$

and

$$w_{n,k} = \frac{1}{2\pi j}\int_C \frac{W^{(k)}(\lambda)}{\lambda^{n+1}}\,d\lambda \tag{16}$$

where

k denotes the order of the system, *i.e.*, the order of the highest linear derivative in the differential equation describing the system;

n is a running discrete positive index taking values 0, 1, 2, · · · ;

$W^{(k)}(\lambda)$ denotes the kth derivative of a time function; and

$w_{n,k}$ denotes the transform of $W^{(k)}(\lambda)$.

This transfomation pair will now be established. In another paper[1] it is shown that in order to develop recursion formulas which will uniquely solve (1), among other things,[7] it is sufficient to partition at the highest-order linear derivative. Following this idea and noting, moreover, the analytic existence of (1), we are entitled to write (15).[8] It should be noted that if any other derivative were selected, one could not ensure obtaining a recurrence relation which would be solvable. Furthermore, if the partition is made at any other derivative, it is easy to show examples of nonlinear differential equations that yield nonconvergent or false results. This difficulty does not arise in linear systems; hence, one can assume a power series solution for such systems.

Eq. (15) is an infinite series uniformly convergent in some circle. Generally, since $W(\lambda)$ is an entire function of exponential type, the circle is the entire λ-plane. This usually occurs in the physical nondissipationless networks. As a consequence we require

$$w_{n,k} = 0 \quad \text{when} \quad n < 0 \text{ and for all } k. \tag{17}$$

Multiplying both members of (15) by λ^{-m-1} gives

$$\lambda^{-m-1}W^{(k)}(\lambda) = \lambda^{-m-1}\sum_{n=0}^{\infty} w_{n,k}\lambda^n \tag{18}$$

where $m>0$ and is an integer. Since n is only a running index of the sum, (18) may be written

$$\lambda^{-m-1}W^{(k)}(\lambda) = \sum_{n=0}^{\infty} w_{n,k}\lambda^{n-m-1}. \tag{19}$$

Let us select a suitable circular-closed contour C in the λ-plane with its center at the origin, the radius of which is such that all the poles of $\lambda^{-m-1}W^{(k)}(\lambda)$ are enclosed. With this contour C we integrate (19):

$$\frac{1}{2\pi j}\int_C \frac{W^{(k)}(\lambda)}{\lambda^{m+1}}\,d\lambda = \frac{1}{2\pi j}\int_C \sum_{n=0}^{\infty} w_{n,k}\lambda^{n-m-1}d\lambda. \tag{20}$$

Since (15) is uniformly convergent, the order of summation and integration may be interchanged. This gives

$$\frac{1}{2\pi j}\int_C \frac{W^{(k)}(\lambda)}{\lambda^{m+1}}\,d\lambda = \sum_{n=0}^{\infty} w_{n,k}\,\frac{1}{2\pi j}\int_C \lambda^{n-m-1}d\lambda. \tag{21}$$

Now consider the integral in the right-hand member of (21). From Cauchy's integral theorem this integral is unity when $n=m$, and zero otherwise. Consequently, the integral is formally recognized as a Kronecker delta function, *i.e.*,

$$\frac{1}{2\pi j}\int_C \lambda^{n-m-1}d\lambda = \delta_{n-m} \tag{22}$$

where

$$\delta_{n-m} = \begin{cases} 1, & n = m \\ 0, & n \neq m \end{cases}. \tag{23}$$

Substituting (22) in (21) yields

$$\frac{1}{2\pi j}\int_C \frac{W^{(k)}(\lambda)}{\lambda^{m+1}}\,d\lambda = \sum_{n=0}^{\infty} w_{n,k}\delta_{n-m} \tag{24}$$

from which (16) immediately follows. Therefore (15) and (16) define a transformation pair. Using this pair, one can develop a table of transforms.

It was pointed out earlier that W replaces x and λ replaces t. Since t is a real variable, x is a function of a real variable. Because of the analytic properties of x we can extend this function by the principle of analytic continuation, thereby giving rise to a function of a complex variable $W(\lambda)$. Ku and Wolf[5] show how one can utilize information obtained in the complex λ-plane to determine the degree of stability of a system along the real half-line t.

---

[7] See Section II.

[8] The right member of (15) is uniformly convergent in some circle in the λ-plane, the center of which is at the origin.

V. OPERATIONAL PROPERTIES

We note that the Taylor-Cauchy transforms satisfy the following operational properties:

$$\mathfrak{J}_c\{\mathfrak{J}_c^{-1}[1]\} = \mathfrak{J}_c^{-1}\{\mathfrak{J}_c[1]\} \tag{25}$$

$$\mathfrak{J}_c[F(\lambda)] \neq F(\lambda)\cdot\mathfrak{J}_c[1] \tag{26}$$

$$\mathfrak{J}_c[0] = 0\cdot\mathfrak{J}_c[1] = 0 \tag{27}$$

$$\mathfrak{J}_c(1) = \delta_n \text{ (Kronecker's delta function)} \tag{28}$$

$$\mathfrak{J}_c^{-1}[1] = \frac{1}{1-\lambda} \quad \text{in } |\lambda| < 1 \tag{29}$$

$$D\cdot\mathfrak{J}_c^{-1}[1] \neq \mathfrak{J}_c^{-1}[D\cdot 1]. \tag{30}$$

We note in (30) particularly that

$$D\cdot\mathfrak{J}_c^{-1}[1] = \frac{d}{d\lambda}\left(\frac{1}{1-\lambda}\right) \quad \text{(from 29)}$$

so that

$$D\cdot\mathfrak{J}_c^{-1}[1] = \frac{-1}{(1-\lambda)^2} \tag{31}$$

and

$$D^n\cdot\mathfrak{J}_c^{-1}[1] = \frac{(-1)^n}{(1-\lambda)^{n+1}}\cdot \tag{32}$$

We also note that

$$D^{-1}\cdot\mathfrak{J}_c^{-1}[1] = -\log\left(\frac{1}{1-\lambda}\right) = \log(1-\lambda). \tag{33}$$

VI. EXAMPLES OF TAYLOR-CAUCHY TRANSFORM PAIRS

A. *Operational Pairs: The Mates* $F(\lambda)\Leftrightarrow f_n$

1) Additivity:[9]

$$\mathfrak{J}_c[F_1(\lambda)+F_2(\lambda)] = \mathfrak{J}_c[F_1(\lambda)] + \mathfrak{J}_c[F_2(\lambda)]$$

Proof:

$$\mathfrak{J}_c[F_1(\lambda)+F_2(\lambda)] = \frac{1}{2\pi j}\int_C \frac{F_1(\lambda)+F_2(\lambda)}{\lambda^{n+1}}\,d\lambda. \tag{34}$$

Since the integral of a sum is equal to the sum of its integrals,

$$\mathfrak{J}_c[F_1(\lambda)+F_2(\lambda)] = \mathfrak{J}_c[F_1(\lambda)] + \mathfrak{J}_c[F_2(\lambda)]. \tag{35}$$

2) Commutivity:[10]

$$\mathfrak{J}_c[aF(\lambda)] = a\mathfrak{J}_c[F(\lambda)]$$

Proof:

$$\mathfrak{J}_c[aF(\lambda)] = \frac{1}{2\pi j}\int_C \frac{aF(\lambda)}{\lambda^{n+1}}\,d\lambda = a\mathfrak{J}_c[F(\lambda)]. \tag{36}$$

3) Change of Scale:

$$\mathfrak{J}_c\left[F\left(\frac{\lambda}{a}\right)\right] = \frac{\mathfrak{J}_c[F(\lambda)]}{a^n}$$

Proof:

$$\mathfrak{J}_c\left[F\left(\frac{\lambda}{a}\right)\right] = \frac{1}{2\pi j}\int_C F\left(\frac{\lambda}{a}\right)\lambda^{-n-1}d\lambda. \tag{37}$$

Let $\zeta=\lambda/a$. Hence, $d\zeta=d\lambda/a$ and the right member of (37) becomes

$$\frac{1}{2\pi j}\int_C F(\zeta)(\zeta a)^{-n-1}a\,d\zeta = \frac{1}{2\pi j}\int_C \frac{F(\zeta)}{a^n\zeta^{n+1}}\,d\zeta \tag{38}$$

so that

$$\mathfrak{J}_c\left[F\left(\frac{\lambda}{a}\right)\right] = a^{-n}\mathfrak{J}_c[F(\lambda)]. \tag{39}$$

4) Initial Value:

$$\lim_{\lambda\to 0} F(\lambda) = \lim_{n\to 0} f_n.$$

This follows immediately from the definition of the direct transform.

B. *Terms Involving* λ^m

1) $\mathfrak{J}_c[\lambda^m] = \delta_{n-m}$, where $n, m = 0, 1, 2, \cdots$.

Thus

$$\mathfrak{J}_c[\lambda^m] = \frac{1}{2\pi j}\int_C \lambda^{m-n-1}d\lambda = \delta_{n-m}. \tag{40}$$

2) $\mathfrak{J}_c[\lambda^m]=0$ when m is nonintegral.

This result follows from (40), noting that n is always integral-valued.

C. *Terms in* $W^{(k-m)}(\lambda)$

1)
$$\mathfrak{J}_c[W^{(k-1)}(\lambda)] = \frac{w_{n-1,k}}{n} + A_{k-1}\delta_n. \tag{41}$$

If $W^{(k)}(\zeta)$ is the kth derivative of W with respect to ζ and is analytic in a region of the ζ-plane, and if 0 and λ are the terminal points of any path lying within this analytic region,

---

[9] This signifies that the operator is distributive with respect to addition and assumes that both terms in the right-hand member exist.

[10] This signifies that the operator is commutative with respect to multiplication by a constant.

$$\int_0^\lambda W^{(k)}(\zeta)d\zeta = W^{(k-1)}(\lambda) - W^{(k-1)}(0) \tag{42}$$

or

$$W^{(k-1)}(\lambda) = \int_0^\lambda W^{(k)}(\zeta)d\zeta + A_{k-1} \tag{43}$$

where

$$A_{k-1} = W^{(k-1)}(0). \tag{44}$$

Substituting (15) into (43) gives, on interchanging the order of summation and integration,

$$W^{(k-1)}(\lambda) = \sum_{n=0}^{\infty} \frac{w_{n,k}}{n+1} \lambda^{n+1} + A_{k-1}. \tag{45}$$

Transforming (45) according to (16) yields

$$\begin{aligned} \mathfrak{Z}_c[W^{(k-1)}(\lambda)] &= \frac{1}{2\pi j}\int_C \sum_{m=0}^{\infty} \frac{w_{m,k}}{m+1} \lambda^{m+1}\lambda^{-n-1}d\lambda \\ &\quad + \frac{1}{2\pi j}\int_C A_{k-1}\lambda^{-n-1}d\lambda \\ &= \frac{w_{n-1}}{n} + A_{k-1}\delta_n. \end{aligned} \tag{46}$$

2) $\mathfrak{Z}_c[W^{(k-2)}(\lambda)] = \frac{w_{n-2,k}}{n(n-1)} + A_{k-1}\delta_{n-1} + A_{k-2}\delta_n.$

If $W^{(k)}(\zeta)$ is analytic in a region of the ζ-plane, then all its derivatives exist and are analytic therein. Consequently,

$$W^{(k-2)}(\lambda) = \int_0^\lambda W^{(k-1)}(\zeta)d\zeta + A_{k-2} \tag{47}$$

where

$$A_{k-2} = W^{(k-2)}(0). \tag{48}$$

Substituting (45) into (47) and performing the indicated integration gives

$$W^{(k-2)}(\lambda) = \sum_{n=0}^{\infty} \frac{w_{n,k}}{(n+1)(n+2)} \lambda^{n+2} + A_{k-1}\lambda + A_{k-2}. \tag{49}$$

Transforming (49) according to (16) yields

$$\begin{aligned} &\mathfrak{Z}_c[W^{(k-2)}(\lambda)] \\ &= \frac{1}{2\pi j}\int_C \sum_{m=0}^{\infty} \frac{w_{m,k}}{(m+1)(m+2)} \lambda^{m+2}\lambda^{-n-1}d\lambda \\ &\quad + \frac{1}{2\pi j}\int_C A_{k-1}\lambda\lambda^{-n-1}d\lambda + \frac{1}{2\pi j}\int_C A_{k-2}\lambda^{-n-1}d\lambda \\ &= \frac{w_{n-2,k}}{n(n-1)} + A_{k-1}\delta_{n-1} + A_{k-2}\delta_n. \end{aligned} \tag{50}$$

3) $\mathfrak{Z}_c[W^{(k-r)}(\lambda)]$

$$= \frac{w_{n-r,k}}{n(n-1)\cdots(n-r+1)} + \sum_{q=1}^{r} \frac{A_{k-q}}{(r-q)!}\delta_{n-r+q}.$$

Proceeding as in the previous cases, we integrate $W^{(k)}(\lambda)$ r times. This gives

$$\begin{aligned} W^{(k-r)}(\lambda) &= \sum_{n=0}^{\infty} \frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r)} \lambda^{n+r} \\ &\quad + \sum_{q=1}^{r} \frac{A_{k-q}}{(r-q)!}\lambda^{r-q} \end{aligned} \tag{51}$$

in which

$$A_{k-q} = W^{(k-q)}(0). \tag{52}$$

Now (51) is transformed according to (16) giving

$$\begin{aligned} &\mathfrak{Z}_c[W^{(k-r)}(\lambda)] \\ &= \frac{1}{2\pi j}\int_C \sum_{m=0}^{\infty} \frac{w_{m,k}}{(m+1)(m+2)\cdots(m+r)} \lambda^{m+r-n-1} d\lambda \\ &\quad + \frac{1}{2\pi j}\int_C \sum_{q=1}^{r} \frac{A_{k-q}}{(r-q)!}\lambda^{r-q-n-1}d\lambda \\ &= \frac{w_{n-r,k}}{n(n-1)(n-2)\cdots(n-r+1)} \\ &\quad + \sum_{q=1}^{r} \frac{A_{k-q}}{(r-q)!}\delta_{n-r+q}. \end{aligned} \tag{53}$$

4) $\mathfrak{Z}_c[W(\lambda)] = \frac{w_{n-k,k}}{n(n-1)\cdots(n-k+1)}$

$$+ \sum_{q=1}^{k} \frac{A_{k-q}}{(k-q)!}\delta_{n-k-q}.$$

This is a special case of (53) in which $r=k$.

D. Terms in $\lambda^\rho W^{(k-r)}(\lambda)$

1) $\mathfrak{Z}_c[\lambda^\rho W^{(k)}(\lambda)] = w_{n-\rho,k}.$

To obtain this transform, first multiply (15) by λ^ρ. Then applying the $\mathfrak{Z}_c$-transform gives

$$\mathfrak{Z}_c[\lambda^\rho W^{(k)}(\lambda)] = \frac{1}{2\pi j}\int_C \sum_{m=0}^{\infty} w_{m,k}\lambda^{m+\rho-n-1}d\lambda = w_{n-\rho,k}. \tag{54}$$

The latter result is obtained on interchanging the order of summation and integration, which is justified because of the uniformity of convergence of the sum.

2) $\mathfrak{Z}_c[\lambda^\rho W^{(k-r)}(\lambda)]$

$$= \frac{w_{n-r-\rho,k}}{(n-\rho)(n-\rho-1)\cdots(n-\rho-r+1)}$$

$$+ \sum_{q=1}^{r} \frac{A_{k-q}}{(r-q)!}\delta_{n-\rho-r+q}.$$

To obtain this result proceed as before by first multiplying $W^{(k-r)}(\lambda)$ by λ^p and then transforming, so that

$$\mathfrak{T}_c[\lambda^p W^{(k-r)}(\lambda)] = \frac{1}{2\pi j}\int_C \sum_{m=0}^{\infty} \frac{w_{m,k}}{(m+1)\cdots(m+r)}\,d\lambda + \frac{1}{2\pi j}\int_C \sum_{q=1}^{r} \frac{A_{k-q}}{(r-q)!}\lambda^{r-q+p-n-1}d\lambda \tag{55}$$

which yields the above result on integration.

E. Transforms of Nonlinear Terms

In the previous paragraphs we have illustrated the use of the Taylor-Cauchy transform to obtain transform mates of linear terms. Now we show how to obtain corresponding mates of nonlinear terms.

1) The Convolution Sums: The higher convolution sums were developed by Wolf in other papers.[1–3] Here we shall collect for reference some of these sums.

Let $C_{n,k,0}^{(\nu)}$ symbolize a transform of the zeroth derivative of a function raised to the νth power. The superscript ν in this case does not represent a derivative as it would in the time function. The subscript 0 refers to the zeroth derivative, and the n and k are defined as previously.

In general let $C_{n,k,0,1,2,\cdots m}^{(\mu)}$ symbolize the transform of the product of the zeroth, first, $\cdots$, and μth derivatives of a given time function. For our purposes let us define

$$C_{n,k,k-r} = \frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r)}. \tag{56}$$

Eq. (56) is a relation between the linear term $w_{n,k}$ and the linear term $C_{n,k,k-r}$. The superscript $\nu=1$ is omitted. When $\nu=0$ the corresponding C is a Kronecker delta function, and the symbol for the latter will always be used instead. Thus

$$C_{n,k}^{(0)} = \delta_n \tag{57}$$

or

$$C_{n-m,k}^{(0)} = \delta_{n-m}. \tag{58}$$

We now develop the higher-order functions of C in terms of its linear function (56):

$$C_{n,k,k-r}^{(2)} = \sum_{q_1=0}^{n} C_{q_1,k,k-r}\, C_{n-q_1,k,k-r}. \tag{59}$$

To display the convolution property sharply, let $k=r$ and drop the second subscript, k. Then (59) becomes

$$C_n^{(2)} = \sum_{q_1=0}^{n} C_{q_1}C_{n-q_1}. \tag{60}$$

$C_n^{(3)}$ and $C_n^{(4)}$ may be written as

$$C_n^{(3)} = \sum_{q_2=0}^{n}\sum_{q_1=0}^{q_2} C_{q_1}C_{q_2-q_1}C_{n-q_2} \tag{61}$$

$$C_n^{(4)} = \sum_{q_3=0}^{n}\sum_{q_2=0}^{q_3}\sum_{q_1=0}^{q_2} C_{q_1}C_{q_2-q_1}C_{q_3-q_2}C_{n-q_3}. \tag{62}$$

In general

$$C_n^{(\nu)} = \sum_{q_{\nu-1}=0}^{n} \cdots \sum_{q_2=0}^{q_3}\sum_{q_1=0}^{q_2} C_{q_1}C_{q_2-q_1}\cdots C_{n-q_{\nu-1}}. \tag{63}$$

Eqs. (60)–(63) display the general procedure for writing convolution sums. We note that the C's which go inside the summations depend on the nature of the problem. Thus (59) shows a case where the C's are obtained from the nonlinearity of degree two in the $(k-r)$th derivative of a function.

In writing the above equations q denotes a running index with the subscript of q denoting a particular running index. The latter subscript is always one less than the order of the C in the left member, and the number of sums is also one less than the order of the C in the left member. We note also that the C's inside the summation sign have subscripts beginning with q_1. The next subscript is found by subtracting the running index of the inside summation from its upper bound, namely, q_2-q_1. The process is continued until all the necessary sums are written.

2) Certain Simplifying Procedures in Subscripts and Equations: If k is taken to be the order of the highest derivative of the nonlinear differential equation under analysis, then it turns out that the w's become independent of the second subscript, k, if all the terms are referred to the second subscript. To illustrate this, assume $k=2$. Then the following pairs result for the second and first derivatives in the absence of initial conditions:

$$W^{(2)}(\lambda) \Leftrightarrow w_{n,2} \tag{64}$$

and

$$W^{(1)}(\lambda) \Leftrightarrow w_{n,1}. \tag{65}$$

If (65) is developed in terms of the highest-order derivative, *i.e.*, $k=2$, it becomes

$$W^{(1)}(\lambda) \Leftrightarrow \frac{w_{n,2}}{n} = w_{n,1}. \tag{66}$$

It is evident that if (64) and (66) are used, the symbol $w_{n,2}$ is now independent of $k(=2)$. To show this further consider the following example of a third-order system:

$$\dddot{x} + \ddot{x} + x\ddot{x} = b \tag{67}$$

subject to the conditions at $t=0$

$$x(0) = a \tag{67a}$$

$$\dot{x}(0) = b \tag{67b}$$

$$\ddot{x}(0) = 0. \tag{67c}$$

Replacing x by W and t by λ as described above and applying the Taylor-Cauchy transform, one obtains the following recursion formula:

$$w_{n,3} = -C^{(2)}_{n-4,3,0,2} - b\frac{w_{n-2,3}}{n-1} - a\frac{w_{n-1,3}}{n} - \frac{w_{n-2,3}}{n(n-1)} - \frac{w_{n-1,3}}{n} \tag{68}$$

where

$$C^{(2)}_{n-4,3,0,2} = \sum_{q_1=0}^{n-4} \frac{w_{q_1,3}w_{n-q_1-4,3}}{(q_1+1)(q_1+2)(q_1+3)(q_1-n-3)}. \tag{69}$$

We note that on referring everything to the third derivative the subscript $k(=3)$ is superfluous since w is independent of k under these conditions. *Therefore, whenever the terms in the transform are all referred to the highest order derivative we shall drop the second subscript, k, so that $w_{n,3}$ becomes simply w_n in this example.*

3) *Certain Nonlinear Transform Pairs Containing Terms in* $[W^{(k-r)}(\lambda)]^\nu$:

a) *Zero initial conditions:* Given $A_{k-1}=A_{k-2}=\cdots=A_{k-r}=0$, then

$$[W^{(k-r)}(\lambda)]^\nu = \left[\sum_{n=0}^{\infty} C_{n,k,k-r}\lambda^{n+r}\right]^\nu \tag{70}$$

where $C_{n,k,k-r}$ is defined by (56). First factor out λ^r, to give

$$[W^{(k-r)}(\lambda)]^\nu = \lambda^{\nu r}\left[\sum_{n=0}^{\infty} C_{n,k,k-r}\lambda^{n}\right]^\nu. \tag{71}$$

Utilizing the results of Section VI-E, 1) on convolution sums, we may write (71) as[11]

$$[W^{(k-r)}(\lambda)]^\nu = \lambda^{\nu r}\sum_{n=0}^{\infty} C^{(\nu)}_{n,k,k-r}\lambda^{n}. \tag{72}$$

Transforming (72) yields

$$\mathfrak{J}_c[\{W^{(k-r)}(\lambda)\}^\nu] = \frac{1}{2\pi j}\int_C \sum_{m=0}^{\infty} C^{(\nu)}_{m,k,k-r}\lambda^{m+\nu r-n-1}\,d\lambda$$
$$= C^{(\nu)}_{n-\nu r,k,k-r}. \tag{73}$$

b) Nonzero Initial Conditions. Given $A_{k-1}\neq A_{k-2}\neq\cdots\neq A_{k-r}\neq 0$,

$$[W^{(k-r)}(\lambda)]^\nu = \left[\sum_{n=0}^{\infty}\frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r)}\lambda^{n+r} + \sum_{q=1}^{r}\frac{A_{k-q}}{(r-q)!}\right]^\nu. \tag{74}$$

Utilizing the binomial theorem, we may write (74) as

$$[W^{(k-r)}(\lambda)]^\nu = \sum_{i=0}^{\nu}\binom{\nu}{i}\left[\sum_{n=0}^{\infty}\frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r)}\lambda^{n+r}\right]^{\nu-i}\cdot\left[\sum_{q=1}^{r}\frac{A_{k-q}}{(r-q)!}\lambda^{r-q}\right]^i$$
$$= \sum_{n=0}^{\infty} C^{(\nu)}_{n-\nu r,k,k-r}\lambda^n + \sum_{n=0}^{\infty}\sum_{i=1}^{\nu-1}\binom{\nu}{i}\sum_{q=1}^{r} C^{(\nu-i)}_{n-(\nu-i+1)r-q,k,k-r}A^{(i)}_{r-q}\lambda^n + \sum_{q=1}^{r} A^{(\nu)}_{r-q}\lambda^{r-q} \tag{75}$$

in which $A^{(i)}_{r-q}$ and $A^{(\nu)}_{r-q}$ are defined generally by

$$A^{(j)}_{r-q} = \sum_{\beta_{j-1}=0}^{r-q}\cdots\sum_{\beta_2=0}^{\beta_3}\sum_{\beta_1=0}^{\beta_2}\frac{A_{k+\beta_1-r}}{\beta_1!}\,\frac{A_{k+\beta_2-\beta_1-r}}{(\beta_2-\beta_1)!}\cdots\frac{A_{k-\beta_{j-1}-q}}{(r-q-\beta_{j-1})!}. \tag{76}$$

Transforming (75) yields the following result:

$$\mathfrak{J}_c[\{W^{(k-r)}(\lambda)\}^\nu] = C^{(\nu)}_{n-\nu r,k,k-r} + \sum_{i=1}^{\nu-1}\sum_{q=1}^{r}\binom{\nu}{i}C^{(\nu-i)}_{n-(\nu-i+1)r-q,k,k-r}A^{(i)}_{r-q} + \sum_{q=1}^{r} A^{(\nu)}_{r-q}\delta_{n-r+q}. \tag{77}$$

In (77) the first term in the right-hand member is the transform of the function for zero initial conditions, the double sum is the transform of the cross products, and the third sum is the transform of the initial conditions raised to the νth power.

4) *Transform of Nonlinear Terms in* $[W^{(k-r_1)}(\lambda)][W^{(k-r_2)}(\lambda)]$:

a) *Zero initial conditions:* Given $A_{k-1}=A_{k-2}=\cdots=A_{k-r_1}=A_{k-r_2}=0$, the product becomes

$$[W^{(k-r_1)}(\lambda)][W^{(k-r_2)}(\lambda)] = \left[\sum_{n=0}^{\infty}\frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r_1)}\lambda^{n+r_1}\right]\cdot\left[\sum_{n=0}^{\infty}\frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r_2)}\lambda^{n+r_2}\right]$$
$$= \sum_{n=0}^{\infty} C^{(2)}_{n,k,k-r_1,k-r_2}\lambda^{n+r_1+r_2} \tag{78}$$

in which the coefficient of λ in (78) is defined as above and is recorded in the Appendix. On transforming (78), we obtain

$$\mathfrak{J}_c[\{W^{(k-r_1)}(\lambda)\}\{W^{(k-r_2)}(\lambda)\}] = C^{(2)}_{n-r_1-r_2,k,k-r_1,k-r_2}. \tag{79}$$

---

[11] For convenience $C^{(\nu)}_{n,k,k-r}$ is defined in Table I, page 921. The second subscript, k, is dropped there in accordance with Section VI-E, 2).

b) *Nonzero initial conditions:* Given $A_{k-1} \neq A_{k-2} \neq \cdots \neq A_{k-r_1} \neq \cdots \neq A_{k-r_2} \neq 0$ and $r_2 > r_1$, the product becomes

$$[W^{(k-r_1)}(\lambda)][W^{(k-r_2)}(\lambda)]$$

$$= \left[\sum_{n=0}^{\infty} \frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r_1)} \lambda^{n+r_1} + \sum_{q=1}^{r_1} \frac{A_{k-q}}{(r_1-q)!} \lambda^{r_1-q} \right]$$

$$\cdot \left[\sum_{n=0}^{\infty} \frac{w_{n,k}}{(n+1)(n+2)\cdots(n+r_2)} \lambda^{n+r_2} + \sum_{q=1}^{r_2} \frac{A_{k-q}}{(r_2-q)!} \lambda^{r_2-q} \right]. \tag{80}$$

After multiplying the above sums, applying the technique used previously, and denoting by $A^{(2)}_{n,k,r_1,r_2}$ the sum

$$A^{(2)}_{n,k,r_1,r_2} = \sum_{\beta=0}^{r_1-1} \frac{A_{k+\beta-r_1}}{\beta!} \frac{A_{k+n-\beta-r_2}}{(n-\beta)!} \tag{81}$$

transforming the result yields

$$\mathfrak{J}_c[\{W^{(k-r_1)}(\lambda)\}\{W^{(k-r_2)}(\lambda)\}] = C^{(2)}_{n-r_1-r_2,k,k-r_1,k-r_2}$$

$$+ \sum_{q=1}^{r_2} \frac{A_{k-q}}{(r_2-q)!} \frac{w_{n-r_1-r_2+q,k}}{(n-r_1-r_2+q+1)(n-r_1-r_2+q+2)\cdots(n-r_2+q)}$$

$$+ \sum_{q=1}^{r_1} \frac{A_{k-q}}{(r_1-q)!} \frac{w_{n-r_1-r_2+q,k}}{(n-r_1-r_2+q+1)(n-r_1-r_2+q+2)\cdots(n-r_1+q)}$$

$$+ \sum_{m=0}^{r_1+r_2-2} A^{(2)}_{m,k,r_1,r_2} \delta_{n-m}. \tag{82}$$

In a similar manner transforms for higher-order products of nonlinear and linear terms may be obtained. Taylor-Cauchy transform pairs are given in Tables II–IV on pages 921–922.

VII. Application of Taylor-Cauchy Transform to Solution of Nonlinear Differential Equations Arising from Circuits

Example 1: Consider a series *RL* circuit shown in Fig. 1. The inductor, *L*, is linear; while the resistor, *R*, is nonlinear, varying in direct proportion to the instantaneous current flowing through it. If the circuit is initially quiescent and a unit voltage step is applied at $t=0$, the resulting nonlinear differential equation is

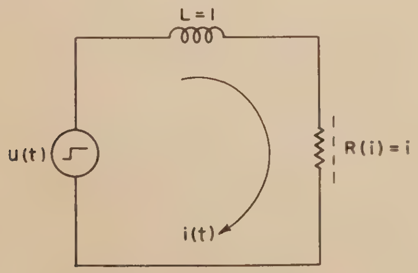

Fig. 1—First-order nonlinear circuit.

$$\frac{di}{dt} + i^2 = u(t) \tag{83}$$

for $L=1$ and $R=i$, where $u(t)$ is the unit step defined in the conventional manner. Also,

$$i(0) = 0. \tag{84}$$

Since (83) is a first-order equation, $k=1$.

Writing $W^{(1)}(\lambda)$ for di/dt and $[W(\lambda)]^2$ for i^2 gives

$$W^{(1)}(\lambda) + [W(\lambda)]^2 = 1 \tag{85}$$

and

$$A_0 = 0. \tag{86}$$

Transforming (85) with the aid of Table III appearing at the end of the paper leads to

$$w_n + C^{(2)}_{n-2,0} = \delta_n \tag{87}$$

in which

$$C^{(2)}_{n-2,0} = \sum_{\beta=0}^{n-2} \frac{w_\beta}{\beta+1} \frac{w_{n-\beta-2}}{n-\beta-1}. \tag{88}$$

We note that the subscript $k(=1)$ is dropped in accordance with the remarks in Section VI-E, 2). Thus

$$w_{n,1} = w_n. \tag{89}$$

Solving (87) and (88) for w_n gives, recursively,

$$w_0 = 1$$

$$w_1 = 0$$

$$w_2 = -1$$

$$w_3 = 0$$

$$w_4 = \frac{2}{3}$$

$$w_5 = 0$$

$$w_6 = -\frac{17}{45}. \qquad (90)$$

$$\cdots$$

Since

$$W(\lambda) = \sum_{n=1}^{\infty} \frac{w_{n-1}}{n} \lambda^n + A_0 \qquad (91)$$

for this case, the solution is obtained on substituting (86) and (90) into (91):

$$W(\lambda) = \lambda - \frac{\lambda^3}{3} + \frac{2}{15}\lambda^5 - \frac{17}{315}\lambda^7 + \cdots. \qquad (92)$$

But (92) is recognized as the series expansion of the hyperbolic tangent. Hence

$$W(\lambda) = \tanh \lambda \qquad (93)$$

and

$$i(t) = \tanh t \qquad (94)$$

Example 2: Consider the nonlinear circuit shown in Fig. 2 having the initial conditions

$$i(0) = -1 \qquad (95)$$

$$v_c(0) = 1 \qquad (96)$$

with parameters as shown and a forcing function $V = \frac{1}{2}e^{-2t}$. The nonlinear integro-differential equation of this circuit is, on applying the initial conditions,

$$\frac{di}{dt} + \left(2 + \frac{i}{2}\right) i + \int_0^t i \, d\tau + 1 = \frac{1}{2} e^{-2t}. \qquad (97)$$

We note that using (95) together with (97) gives

$$\frac{di(0)}{dt} = 1. \qquad (98)$$

Clearing (97) of integrals by differentiating yields

$$\frac{d^2 i}{dt^2} + (2 + i)\frac{di}{dt} + i = -e^{-2t}. \qquad (99)$$

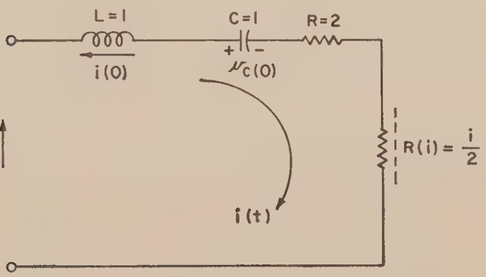

Fig. 2—Second-order nonlinear circuit.

Now we see that $k = 2$. Thus writing $W^{(2)}(\lambda)$ for $d^2 i/dt^2$, $W^{(1)}(\lambda)$ for di/dt, and $W(\lambda)$ for i leads to the equation

$$W^{(2)}(\lambda) + 2W^{(1)}(\lambda) + [W^{(1)}(\lambda)][W(\lambda)] + W(\lambda) = -e^{-2\lambda} \qquad (100)$$

with

$$A_0 = -1 \qquad (101)$$

$$A_1 = 1. \qquad (102)$$

Applying the Taylor-Cauchy transform with the aid of Table III gives

$$w_n = -\frac{(-2)^n}{n!} - 2\delta_{n-1} - \frac{w_{n-1}}{n} - 2\frac{w_{n-2}}{n(n-1)} - \frac{w_{n-2}}{n-1} - C^{(2)}_{n-3,1,0} \qquad (103)$$

where

$$C^{(2)}_{n-3,1,0} = \sum_{\beta=0}^{n-3} \frac{w_\beta}{\beta+1} \frac{w_{n-\beta-3}}{(n-\beta-2)(n-\beta-1)}. \qquad (104)$$

Solving (103) and (104) recursively for w_n gives

$$w_0 = -1$$

$$w_1 = 1$$

$$w_2 = -\frac{1}{2}$$

$$w_3 = \frac{1}{3!}$$

$$w_4 = -\frac{1}{4!} \qquad (105)$$

$$\cdots.$$

Since

$$W^{(k-2)}(\lambda) = W(\lambda) = \sum_{n=2}^{\infty} \frac{w_{n-2}}{n(n-1)} \lambda^n + A_1\lambda + A_0 \qquad (106)$$

substituting (101), (102), and (105) in (106) yields the result

$$W(\lambda) = -1 + \lambda - \frac{\lambda^2}{2!} + \frac{\lambda^3}{3!} - \frac{\lambda^4}{4!} + \cdots. \qquad (107)$$

The latter equation is recognized as the series expansion for $-e^{-\lambda}$. Hence

$$i(t) = -e^{-t}. \qquad (108)$$

VIII. CONCLUSION AND COMMENTS

This paper has presented a transform method for solving a certain class of ordinary nonlinear differential equations. The method essentially converts a given nonlinear differential equation into a corresponding algebraic equation which can be solved recursively. Under certain conditions, namely, when the general term can be found, the solution can be put in closed form.

It turns out that this method comprises an elegant transform method yielding the same results as the partition method. Actually the method given here is another way of looking at the partition method with a powerful mathematical probe. The Taylor-Cauchy transform is related in a general way to the Mellin-Stieltjes transform.[12,13]

The transform is particularly suited for the analysis of systems with randomly varying inputs.[14] With the transform the randomness is transferred from the continuous functions to discrete functions, thus enabling one to utilize the vast body of material available for the analysis of discrete random processes.

The analysis of linear time-varying systems is also easily handled. It appears that such systems can be analyzed in closed form, or at least an analytic description can be given of the behavior of the stability accurately in the complex frequency plane.

ACKNOWLEDGMENT

The authors wish to acknowledge the support extended them by the National Science Foundation in making these studies in nonlinear-system theory. They also wish to thank Drs. J. G. Brainerd and Harry Sohon for their interest and encouragement in this work.

Laurent-Cauchy Transforms for Analysis of Linear Systems Described by Differential-Difference and Sum Equations[*]

Y. H. KU[†], SENIOR MEMBER, IRE, AND A. A. WOLF[‡], MEMBER, IRE

Summary—**The Taylor-Cauchy transform for the analysis of nonlinear systems was presented at the 1959 IRE National Convention.[1] In this paper it is shown that the Laurent-Cauchy transform can be derived from the Taylor-Cauchy transform by a simple mapping. Whereas a complex λ plane is used in the Taylor-Cauchy transform, a complex ρ plane is used in the Laurent-Cauchy transform where the two complex variables are related by $\lambda = 1/\rho$. In the Taylor-Cauchy transform method, $W^{(k)}(\lambda)$, the kth derivative of $W(\lambda)$, converges inside a circle. However, in the Laurent-Cauchy transform method, $H(\rho)$ converges outside of a circle of radius R. Thus, $W^{(k)}(\lambda)$ is expressible by a Taylor series whose general term is**

$$\sum_{n=0}^{\infty} w_{n,k}\lambda^{n}$$

and $H(\rho)$ is expressible by a Laurent series whose general term is

$$\sum_{n=0}^{\infty} h_{n}\rho^{-n}.$$

In either case, the relation between the coefficients of the power series and the function of a complex variable is given by Cauchy's integral. In conjunction with the Laplace transform, the Laurent-Cauchy transform can be used to analyze discrete-continuous systems such as digital servomechanisms, retarded feedback control systems, certain analog-digital computer systems, and pulsed-data systems. If n is replaced by nT, where T is a sampling time, and h_n is taken to mean $h(nT)$, the Laurent-Cauchy transform reduces to the Z-transform. A table of Laurent-Cauchy transforms, several theorems, and three examples are given in the paper.

I. INTRODUCTION

IN a previous work[1] a transform method, the Taylor-Cauchy transform, was developed as a formal consequence of a mathematical theory for analysis of nonlinear systems.[2–5] The Taylor-Cauchy transform method was presented at the 1959 IRE National Convention, and now appears as a companion paper in this issue. This method, the Taylor-Cauchy transform, is one member of a broad class of transforms which correspond to a given class of generalized or modified forcing functions. Another member of this class of transforms is developed in this paper. The new transform method, the Laurent-Cauchy transform, can be derived from the Taylor-Cauchy transform by a simple mapping. A new complex variable ρ, used in the Laurent-Cauchy transform, is related to the complex variable λ, used in the Taylor-Cauchy transform, by the simple relation $\lambda = 1/\rho$. In the Taylor-Cauchy transform method, $W^{(k)}(\lambda)$, the kth derivative of $W(\lambda)$, converges inside a circle. In the Laurent-Cauchy transform method, $H(\rho)$, a function of the complex variable ρ, converges outside a circle of radius R. Thus $W^{(k)}(\lambda)$ is expressible by a Taylor series whose general term is

$$\sum_{n=0}^{\infty} w_{n,k}\lambda^{n}$$

whereas $H(\rho)$ is expressible by a Laurent series whose general term is

$$\sum_{n=0}^{\infty} h_{n}\rho^{-n}.$$

Just as $w_{n,k}$ is related to $W^{(k)}(\lambda)$ by the Cauchy integral, so it is shown that h_n is related to $H(\rho)$ by the Cauchy integral with a different contour.

The Laurent-Cauchy transform is particularly useful in the analysis of physical systems described by differential-difference and sum equations. Used in conjunction with the Laplace transform, it makes possible the analysis of discrete-continuous systems such as digital servomechanisms, retarded feedback control systems, certain analog-digital computer systems, and pulsed-data systems. In addition, if the input is a random process, the Laurent-Cauchy transform can be used with the transform-ensemble method[6] to obtain information about the statistics of the response of the discrete systems.

II. DERIVATION OF THE LAURENT-CAUCHY TRANSFORM FROM THE TAYLOR-CAUCHY TRANSFORM

The Taylor-Cauchy transform pair[1] is given by (1) and (2) below:

$$w_{n,k} = \frac{1}{2\pi j}\int_{C'} \frac{W^{(k)}(\lambda)}{\lambda^{n+1}}\, d\lambda \tag{1}$$

$$W^{(k)}(\lambda) = \sum_{n=0}^{\infty} w_{n,k}\lambda^{n} \tag{2}$$

where

$w_{n,k}$ denotes the direct Taylor-Cauchy transform of $W^{(k)}(\lambda)$,

$W^{(k)}(\lambda)$ denotes the kth derivative of a complex time function $W(\lambda)$,

$W(\lambda)$ denotes a function of the complex variable λ corresponding to a function of the real time variable t,

n denotes the real discrete variable in the transform half-line corresponding to the complex time variable λ in the complex time plane,

λ denotes a complex time variable corresponding to the real time variable t, and

C' denotes a contour in the λ-plane defining the domain of definition of the complex time function $W(\lambda)$ and enclosing the singularities of the integrand of (1).

Consider now the transformation given below:

$$\lambda = \frac{1}{\rho} \tag{3}$$

where ρ defines a complex frequency variable in the complex ρ-plane. Eq. (3) is a bilinear transformation with the property that points inside the unit circle in the λ-plane map into corresponding points outside the unit circle in the ρ-plane. The differential of λ is given by

$$d\lambda = -\frac{d\rho}{\rho^2}\cdot \tag{4}$$

Substituting (3) and (4) into (1) and (2) yields

$$w_{n,k} = \frac{1}{2\pi j}\int_C W^{(k)}\left(\frac{1}{\rho}\right)\rho^{n-1}d\rho \tag{5}$$

and

$$W^{(k)}\left(\frac{1}{\rho}\right) = \sum_{n=0}^{\infty} w_{n,k}\rho^{-n}. \tag{6}$$

Let us denote $w_{n,k}$ by $h_{n,q}$ and $W^{(k)}(1/\rho)$ by $H^{(q)}(\rho)$ respectively. Thus

$$h_{n,q} = w_{n,k} \tag{7}$$

$$H^{(q)}(\rho) = W^{(k)}\left(\frac{1}{\rho}\right). \tag{8}$$

Thus, we may write (5) and (6) as

$$h_{n,q} = \frac{1}{2\pi j}\int_C H^{(q)}(\rho)\rho^{n-1}d\rho \tag{9}$$

$$H^{(q)}(\rho) = \sum_{n=0}^{\infty} h_{n,q}\rho^{-n}. \tag{10}$$

The nature and restrictions concerning the functions h_n and $H(\rho)$ are discussed in Section III. The contour C encloses the singularities of $H^{(q)}(\rho)\rho^{n-1}$ corresponding to the contour C' by means of the mapping given in (3). The index q in (8) can be omitted in practical cases. Formally, the index q may denote the qth derivative of $H(\rho)$ with respect to ρ. We allow q to be different from k so that (11) is satisfied:

$$0 \leq q \leq k. \tag{11}$$

For certain applications such as differential-difference and sum equations we have h_n and $H(\rho)$ as functions of time t, a real variable. Thus, after dropping q and introducing t explicitly, we get

$$h_n(t) = \frac{1}{2\pi j}\int_C H(\rho, t)\rho^{n-1}d\rho \tag{12}$$

$$H(\rho, t) = \sum_{n=0}^{\infty} h_n(t)\rho^{-n}. \tag{13}$$

As functions of a real variable t, $h_n(t)$ and $H(\rho, t)$ in (12) and (13) are Laplace transformable. For the sake of clarity, we may keep the symbols h_n and $H(\rho)$ to represent the Laurent-Cauchy transform pairs, irrespective of whether h_n and $H(\rho)$ are functions of t or of their Laplace transforms.

In Table I (Appendix I), q is taken as zero as in (12) and (13). Furthermore, we shall omit t, understanding its presence implicitly. The implication of this selection and other geometric interpretations are given in a note[7] previously published.

III. RESTRICTIONS ON THE FUNCTIONS AND NOTATION

In this section we shall briefly discuss some of the pertinent restrictions on the functions h_n and $H(\rho)$. Let us now rewrite (12) and (13) consistent with the conditions of the last paragraph:

$$h_n = \frac{1}{2\pi j}\int_C H(\rho)\rho^{n-1}d\rho \tag{14}$$

$$H(\rho) = \sum_{n=0}^{\infty} h_n\rho^{-n}. \tag{15}$$

We make the following assumptions.

1) $$h_m = O(r^m) \tag{16}$$

where $r>R>O$, $r=|\rho|$, and

$$R^{-1} = \limsup_{n\to\infty} |h_n|^{1/n}. \tag{17}$$

R is the radius of a circle in the complex ρ-plane outside of which the series of (15) converges.

2) If $h_n = h_n(t)$, then

$$h_n(t) = O(e^{\alpha_n t});\ \alpha_n \text{ constant for each } n. \tag{18}$$

3) $H(\rho)$ converges outside of a circle of radius R.

4) If $H(\rho) = H(\rho, t)$, then

$$H(\rho, t) = O(e^{\beta_\rho t});\quad \beta_\rho \text{ constant for each } \rho. \tag{19}$$

5) The contour C is determined from (17) and (20):

$$\rho = re^{j\theta} \tag{20}$$

---

[7] A. A. Wolf, "On the significance of transients and steady-state behavior in nonlinear systems," PROC. IRE, vol. 47, pp. 1785–1786; October, 1959.

where θ is the angle of direction in the ρ-plane with the center of the circle at the origin, and r is the magnitude of ρ.

We note that (15) can be considered as a means of transforming a function of a discrete variable, h_n, into a continuous function of a complex frequency variable, $H(\rho)$. This mapping is illustrated in Fig. 1.

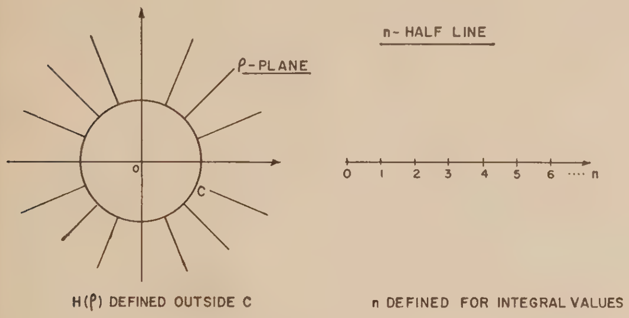

Fig. 1—Mapping of Laurent-Cauchy transform.

IV. APPLICATION OF THE LAURENT-CAUCHY TRANSFORM METHOD

Let us denote the direct Laurent-Cauchy transform and its inverse by the symbols $\mathcal{L}_c$ and $\mathcal{L}_c^{-1}$, respectively. We choose (15) to define $H(\rho)$ as the direct Laurent-Cauchy transform of h_n such that

$$\mathcal{L}_c[h_n] = H(\rho). \tag{21}$$

This is similar to the symbolic relation in Laplace transforms: $\mathcal{L}[y(t)] = Y(s)$, where $y(t)$ is a function of the real variable t and $Y(s)$ is a corresponding function of the complex variable s. The inverse Laurent-Cauchy transform is then defined by (14) and expressed symbolically by (22):

$$\mathcal{L}_c^{-1}[H(\rho)] = h_n. \tag{22}$$

Comparing (14) with the well-known complex integral form of $\mathcal{L}^{-1}[Y(s)]$, we see that in both cases the inverse transform can be obtained by contour integration. Thus, we may consider both the Laurent-Cauchy transform and the Laplace transform (as well as the Fourier transform) as members of a general class of transforms. It is logical to ask whether the Z-transform also belongs to this general class. If n is replaced by nT, where T is a sampling time, and the discrete variable h_n is taken to mean $h(nT)$, we see that (12) and (13) reduce to the Z-transform.

Difference equations are used to approximate the differential equations that describe a continuous system. Mixed difference-differential equations are sometimes encountered. Here we shall consider a more general form given by (23) which may be termed a differential-difference and sum equation:

$$\sum_{m=0}^{M}\sum_{k=0}^{K}\alpha_{km}y_{n+m}^{(k)}(t) + \sum_{k=0}^{n}\beta_k y_k(t) = x_n(t). \tag{23}$$

We desire to determine $y_n(t)$ in terms of α's, β's and the forcing function $x_n(t)$. Note that $y_n^{(k)}(t)$ denotes the kth derivative of $y_n(t)$ with respect to time. An equation like (23) could describe a pulsed data or retarded feedback control system. Letting the Laplace transforms of $y_n(t)$ and $x_n(t)$ be denoted by $h_n(s)$ and $g_n(s)$, respectively,

$$h_n(s) = Y_n(s) = \mathcal{L}[y_n(t)];\ g_n(s) = X_n(s) = \mathcal{L}[x_n(t)]. \tag{24}$$

The Laurent-Cauchy pairs can be given as follows, similar to (12) and (13):

$$h_n(s) = \frac{1}{2\pi j}\int_C H(\rho, s)\rho^{n-1}d\rho \tag{25}$$

$$H(\rho, s) = \sum_{n=0}^{\infty} h_n(s)\rho^{-n}. \tag{26}$$

Similar pairs can be given for $g_n(s)$ and $G(\rho, s)$. Assuming that the system is initially at rest and noting that the Laplace transform of $y_{n+m}^{(k)}(t)$ equals $s^k h_{n+m}(s)$, we apply first the Laplace transform and then the Laurent-Cauchy transform to (23) to give

$$\sum_{m=0}^{M}\sum_{k=0}^{K}\alpha_{km}s^k\mathcal{L}_c[h_{n+m}(s)] + \mathcal{L}_c\left[\sum_{k=0}^{n}\beta_k h_k(s)\right] = \mathcal{L}_c[g_n(s)]. \tag{27}$$

From (26) and Appendix I, we have

$$\mathcal{L}_c[h_n(s)] = H(\rho, s) \tag{28}$$

$$\mathcal{L}_c[h_{n+m}(s)] = \rho^m H(\rho, s) \tag{29}$$

$$\mathcal{L}_c[g_n(s)] = G(\rho, s). \tag{30}$$

In Section VI it is shown that

$$\mathcal{L}_c\left[\sum_{k=0}^{n}\beta_k h_k(s)\right] = \left(\frac{\rho}{\rho - 1}\right)\frac{1}{2\pi j}\int_C \frac{B(\gamma)H\left(\dfrac{\rho}{\gamma}, s\right)}{\gamma}d\gamma \tag{31}$$

where γ denotes a complex variable like ρ, and $B(\gamma)$ is the Laurent-Cauchy transform of β_k. On utilizing (28), (29), (30), and (31) we obtain from (27) the transform equations in ρ and s as follows:

$$H(\rho, s)\sum_{m=0}^{M}\sum_{k=0}^{K}\alpha_{km}s^k\rho^m + \frac{\rho}{\rho - 1}\,\frac{1}{2\pi j}\int_C \frac{B(\gamma)H\left(\dfrac{\rho}{\gamma}, s\right)}{\gamma}d\gamma = G(\rho, s). \tag{32}$$

Eq. (32) is a linear integral equation of the kind which may be solved by a convergent iteration process.[1,2] The general solution of (32) in terms of the elementary functions is not known. Let us examine a special case in which $\beta_k = \beta$ for all $k \geq 0$, where β is a constant. With this condition, (32) simplifies to

$$H(\rho, s)\sum_{m=0}^{M}\sum_{k=0}^{K}\alpha_{km}s^k\rho^m + \frac{\rho\beta}{\rho-1}H(\rho, s) = G(\rho, s). \quad (33)$$

Therefore

$$H(\rho, s) = \frac{G(\rho, s)}{D(\rho, s)} \quad (34)$$

where

$$D(\rho, s) = \sum_{m=0}^{M}\sum_{k=0}^{K}\alpha_{km}s^k\rho^m + \frac{\rho\beta}{\rho-1}\cdot \quad (35)$$

To recover $y_n(t)$, it is necessary first to have a knowledge of the zeros of $D(\rho,s)$ given by (35). Knowing the zeros of $D(\rho, s)$, the residue theorem can be applied first to the inverse Laplace transform and then to the inverse Laurent-Cauchy transform. Formally, this gives

$$y_n(t) = \mathcal{L}_c^{-1}\mathcal{L}^{-1}[H(\rho, s)] = \mathcal{L}^{-1}\mathcal{L}_c^{-1}[H(\rho, s)]. \quad (36)$$

The operators $\mathcal{L}^{-1}$ and $\mathcal{L}_c^{-1}$ are commutative with respect to the operand. In complicated cases the roots of s might involve radicals of the variable ρ and conversely. Thus, higher order singularities may lead to branch points and the solution may then involve transcendental functions of higher order.

V. COMPUTER CONTROLLED FEEDBACK SYSTEM

To illustrate the use of (12), (13), (25) and (26), let us consider an example involving continuous-discrete processes. Referring to Fig. 2, a simple servo is controlled by a computer (shown in Fig. 3) so that its output is suitably modulated. It is possible in this system to separate the continuous process from the discrete process. This is equivalent to saying mathematically that the difference equation is separate from the continuous equation. In such cases, the total solution is usually the product of the separate solutions. In other words, one process amplitude modulates the other. To illustrate the present method, no notice will be made of the separability property from the system configuration. Instead, we shall solve this as a mathematical problem.

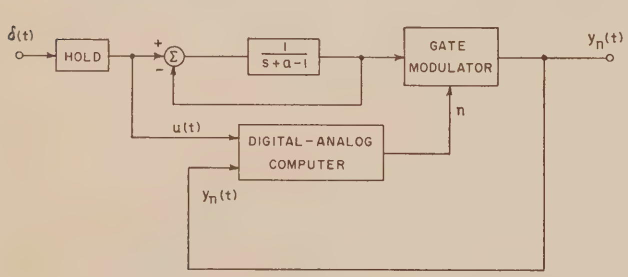

Fig. 2—An exponential pulse response feedback computer control system.

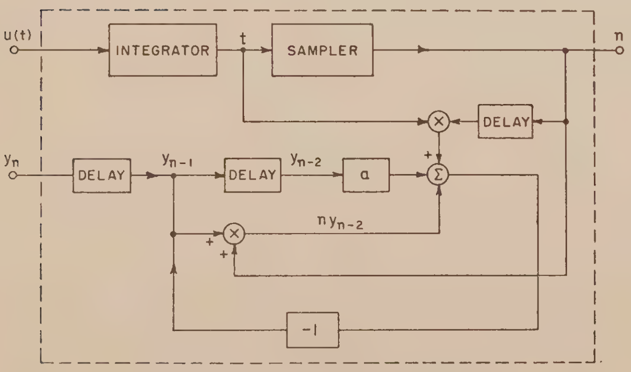

Fig. 3—Digital-analog computer of Fig. 2.

Example 1: Consider the equation

$$y'_{n+1}(t) + \frac{a}{n+1}y_n(t) = 0 \quad (37)$$

where the prime denotes a time derivative, a denotes a constant, and n denotes gate-time pulses taking the discrete values $n=0, 1, 2, \cdots$ only. The initial conditions are

$$y_n(0) = \frac{1}{n!}\cdot \quad (38)$$

Eq. (37) can be rewritten as

$$(n+1)y'_{n+1}(t) + ay_n(t) = 0. \quad (39)$$

Taking the Laplace transform gives

$$\begin{aligned}(n+1)sY_{n+1}(s) + aY_n(s) &= (n+1)y_{n+1}(0)\\ &= \frac{(n+1)}{(n+1)!} = \frac{1}{n!}\cdot \quad (40)\end{aligned}$$

Denoting $Y_n(s)$ by $h_n(s)$ as in (24) and noting $Y_{n+1}(s) = h_{n+1}(s)$, (40) becomes

$$s(n+1)h_{n+1}(s) + ah_n(s) = \frac{1}{n!}\cdot \quad (40a)$$

From Table I (Appendix I) we get

$$\mathcal{L}_c[(n+1)h_{n+1}] = -\rho^2H'(\rho) \quad (41)$$

where $H'(\rho) = dH(\rho)/d\rho$:

$$\mathcal{L}_c\left[\frac{1}{n!}\right] = e^{1/\rho}. \quad (42)$$

Taking the Laurent-Cauchy transform of (40) and utilizing the results of (28), (41) and (42), we get the transform equation

$$-s[\rho^2H'(\rho, s)] + aH(\rho, s) = e^{1/\rho}. \quad (43)$$

Solving for $H(\rho, s)$ gives

$$H(\rho, s) = \frac{e^{1/\rho}}{s+a}\cdot \quad (44)$$

The correctness of the above solution can be checked by noting that $dH/d\rho = (-1/\rho^2)H$ and that the left-hand terms of (43) add up to $(s+a)H(\rho, s)$. Inverting (44) with respect to ρ gives

$$h_n(s) = \frac{1}{n!(s+a)}\cdot \tag{45}$$

Noting that $h_n(s)=Y_n(s)$, according to (24), and taking the inverse Laplace transform, gives

$$y_n(t) = \frac{e^{-at}}{n!}\cdot \tag{46}$$

Eq. (46) signifies a sequence of functions defined for discrete values of $n=0, 1, 2, \cdots$ so that

$$y_0(t) = e^{-at};\ y_1(t) = e^{-at};\ y_2(t) = \frac{e^{-at}}{2};\cdots. \tag{47}$$

Eq. (47) gives the values for the interval corresponding to n. Thus, $y_0(t)$ defines the value for the interval 0 to 1, $y_1(t)$ defines the value for the interval 1 to 2, $y_2(t)$ defines the value for the interval 2 to 3, and so on. The physical implications of such systems will not be discussed here except to say that phenomena exist which decay rapidly with time. Then, a system of pulses which also decay rapidly with time may be useful as a timing reference.

From the above example, we see that by using both the Laplace transform and the Laurent-Cauchy transform we are able to separate the two processes, one continuous and one discrete. The final answer is then found to be the product of the two separate solutions.

VI. DERIVATION OF PRODUCT AND SUM TRANSFORMS

Transform of Sum of Sequence Functions

In certain physical applications it is required to sum a set of n-sequence functions as shown in Fig. 4. A knowledge of the transform of the sum is therefore necessary. Such a sum appears in (23) and its transform is given in (31) and (32). We now show details of obtaining this transform. By definition, as given in (15),

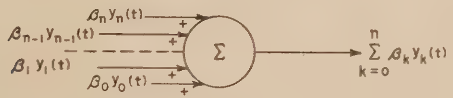

Fig. 4—Summation of time sequence functions.

$$\mathfrak{L}_c\left[\sum_{k=0}^{n}\beta_k h_k(s)\right] = \sum_{n=0}^{\infty}\sum_{k=0}^{n}\beta_k h_k(s)\rho^{-n}. \tag{48}$$

The right-hand member of (48) may be written as

$$\sum_{k=0}^{\infty}\sum_{n=k}^{\infty}\beta_k h_k(s)\rho^{-n}$$

by interchanging the order of summation. Thus (48) becomes

$$\mathfrak{L}_c\left[\sum_{k=0}^{n}\beta_k h_k(s)\right] = \sum_{k=0}^{\infty}\beta_k h_k(s)\sum_{n=k}^{\infty}\rho^{-n}. \tag{49}$$

Now

$$\sum_{n=k}^{\infty}\rho^{-n} = \frac{\rho^{-k}}{1-\rho^{-1}} = \frac{\rho}{\rho-1}\rho^{-k}. \tag{50}$$

Substituting (50) into (49) gives

$$\mathfrak{L}_c\left[\sum_{k=0}^{n}\beta_k h_k(s)\right] = \frac{\rho}{\rho-1}\sum_{k=0}^{\infty}\beta_k h_k(s)\rho^{-k} \tag{51}$$

$$= \frac{\rho}{\rho-1}\mathfrak{L}_c[\beta_k h_k(s)]. \tag{51a}$$

The right-hand member of (51a) is reduced by use of

$$\beta_k = \frac{1}{2\pi j}\int_C B(\gamma)\gamma^{k-1}d\gamma \tag{52}$$

where γ is a complex variable like ρ. Thus

$$\mathfrak{L}_c[\beta_k h_k(s)] = \sum_{k=0}^{\infty}\left[\frac{1}{2\pi j}\int_C B(\gamma)\gamma^{k-1}d\gamma\right]h_k(s)\rho^{-k} \tag{53}$$

$$= \frac{1}{2\pi j}\int_C B(\gamma)\gamma^{-1}\left[\sum_{k=0}^{\infty}h_k(s)\left(\frac{\rho}{\gamma}\right)^{-k}\right]d\gamma. \tag{54}$$

But by definition, as given in (15), we have

$$H\left(\frac{\rho}{\gamma}, s\right) = \sum_{k=0}^{\infty}h_k(s)\left(\frac{\rho}{\gamma}\right)^{-k}. \tag{55}$$

Substituting (55) into (54) and this result into (51a) gives

$$\mathfrak{L}_c\left[\sum_{k=0}^{n}\beta_k h_k(s)\right]$$

$$= \frac{\rho}{\rho-1}\frac{1}{2\pi j}\int_C B(\gamma)\gamma^{-1}H\left[\frac{\rho}{\gamma}, s\right]d\gamma. \tag{56}$$

Eq. (56) is the same as (31) and is the transform of a sum of sequence functions.

Special Case of the Sum of Sequence Functions

Consider a special case of (56), namely, when $\beta_k=\beta$ for all values of k greater or equal to zero. Since β is a constant, we may remove β from under the summation sign. Therefore, we have

$$\mathfrak{L}_c\left[\beta\sum_{k=0}^{n}h_k(s)\right] = \frac{\rho\beta}{\rho-1}\sum_{k=0}^{\infty}h_k(s)\rho^{-k}. \tag{57}$$

Since

$$H(\rho, s) = \sum_{k=0}^{n}h_k(s)\rho^{-k}, \tag{58}$$

substitution of (58) into (57) gives

$$\mathcal{L}_c\left[\beta\sum_{k=0}^{\infty}h_k(s)\right]=\frac{\rho\beta}{\rho-1}H(\rho,s). \tag{59}$$

A number of other transforms appear in Table I on pages 930 and 931. In the table, the variable t is often understood and does not appear explicitly.

VII. SUMMATION THEOREMS

The Laurent-Cauchy transform is very useful in summing certain series, examples of which are

$$\sum_{n=0}^{\infty} f_n, \tag{60}$$

$$\sum_{n=0}^{\infty} f_n y_n, \tag{61}$$

$$\sum_{n=0}^{k} f_n, \tag{62}$$

etc.

The problem of summing such series in a general way has been the subject of works of many prominent mathematicians.[8] We shall show how the following theorems are obtained.

First Summation Theorem

Given a discrete function f_n whose Laurent-Cauchy transform $F(\rho)$ is known. Then

$$\sum_{n=0}^{\infty} f_n=\frac{1}{2\pi j}\int_C \frac{F(\rho)}{\rho(1-\rho)}\,d\rho. \tag{63}$$

Proof: Since

$$f_n=\frac{1}{2\pi j}\int_C F(\rho)\rho^{n-1}d\rho \tag{64}$$

then as

$$\sum_{n=0}^{\infty} f_n=\frac{1}{2\pi j}\int_C F(\rho)\sum_{n=0}^{\infty}\rho^{n-1}d\rho \tag{65}$$

utilizing the summation formula

$$\sum_{n=0}^{\infty}\rho^{n-1}=\rho^{-1}\frac{1}{1-\rho}; \qquad |\rho|<1 \tag{66}$$

we obtain (63).

Second Summation Theorem

Given a discrete function f_n whose $\mathcal{L}_c$-transform is $F(\rho)$. Then

$$\sum_{n=0}^{k} f_n=\frac{1}{2\pi j}\int_C \frac{F(\rho)(1-\rho^{k+1})}{\rho(1-\rho)}\,d\rho. \tag{67}$$

The proof follows a pattern similar to the previous theorem.

Third Summation Theorem

Given two $\mathcal{L}_c$-transformable discrete functions f_n and y_n with $\mathcal{L}_c$-transforms $F(\rho)$ and $Y(\rho)$, then

$$\sum_{n=0}^{\infty} f_n y_n=\frac{1}{2\pi j}\int_C \rho^{-1}F(\rho^{-1})Y(\rho)d\rho. \tag{68}$$

Proof: Let

$$y_n=\frac{1}{2\pi j}\int_{C_1} Y(\rho)\rho^{n-1}d\rho \tag{69}$$

and f_n is defined as before with a contour C_2. Let $C=C_1+C_2$, then

$$y_n f_n=\frac{1}{2\pi j}\int_C Y(\rho)\rho^{n-1}f_n d\rho. \tag{70}$$

Summing both sides of (70) yields

$$\sum_{n=0}^{\infty} y_n f_n=\frac{1}{2\pi j}\int_C Y(\rho)\sum_{n=0}^{\infty}\rho^{n-1}f_n d\rho; \tag{71}$$

utilizing

$$\sum_{n=0}^{\infty} f_n\rho^n=F(\rho^{-1}) \tag{72}$$

we obtain the theorem given in (68).

Other Summation Theorems

We state here the results of two other summation theorems:

$$\sum_{n=0}^{\infty} y_{n+1}\Delta f_n=\frac{1}{2\pi j}\int_C Y(\rho)F(\rho^{-1})\frac{1-\rho}{\rho}\,d\rho \tag{73}$$

and

$$\sum_{n=0}^{\infty} y_n\Delta f_n=\frac{1}{2\pi j}\int_C Y(\rho)F(\rho^{-1})\frac{1-\rho}{\rho^2}\,d\rho \tag{74}$$

where

$$\Delta f_n=f_{n+1}-f_n. \tag{74a}$$

VIII. EXAMPLES

To illustrate some of the above theorems we shall consider the following examples.

Example 2—A Simple Sum: Given $f_n=n$

$$f_n=n \tag{75}$$

$$F(\rho)=\frac{\rho}{(\rho-1)^2}, \tag{76}$$

---

[8] G. Boole, "A Treatise on the Calculus of Finite Differences," G. E. Stechert and Co., New York, N. Y.; 1860.

thus

$$\sum_{n=0}^{k} n = \frac{1}{2\pi j}\int_C \frac{\rho(1-\rho^{k+1})}{(1-\rho)^2(1-\rho)\rho}\,d\rho. \tag{77}$$

Simplifying (77),

$$\sum_{n=0}^{k} n = \frac{1}{2!}\,\frac{d^2}{d\rho^2}\left[\rho^{k-1}-1\right]_{\rho=1} \tag{78}$$

$$\sum_{n=0}^{k} n = \frac{k(k+1)}{2}\,. \tag{79}$$

This result checks the well-known result for this sum.

Example 3—A Simple Product Sum: Consider

$$y_n = a^n \tag{80}$$

$$Y(\rho) = \frac{\rho}{\rho - a} \tag{81}$$

and

$$f_n = \frac{1}{n!} \tag{82}$$

$$F(\rho) = e^{1/\rho} \tag{83}$$

$$F\left(\frac{1}{\rho}\right) = e^{\rho}. \tag{84}$$

Then

$$\sum_{n=0}^{\infty} \frac{a^n}{n!} = \frac{1}{2\pi j}\int_C \rho^{-1}\,\frac{\rho}{\rho-a}\,e^{\rho}d\rho \tag{85}$$

$$= \frac{1}{2\pi j}\int_C \frac{e^{\rho}}{\rho-a}\,d\rho \tag{86}$$

$$= e^{a}. \tag{87}$$

Eq. (87) is known to be correct. The correspondence is evident upon expanding e^a by a Taylor series.

IX. COMPARISON OF LAURENT-CAUCHY AND TAYLOR-CAUCHY TRANSFORMS

The Taylor-Cauchy transform is one member of a general class of transforms useful in the analysis of certain physical systems. It is useful in the analysis of nonlinear systems. The direct Taylor-Cauchy transform is defined by (1) and can be symbolically expressed as

$$\mathfrak{T}_c\left[W^{(k)}(\lambda)\right] = w_{n,k}. \tag{88}$$

The inverse Taylor-Cauchy transform is defined by (2) and can be symbolically expressed as

$$\mathfrak{T}_c^{-1}\left[w_{n,k}\right] = W^{(k)}(\lambda). \tag{89}$$

Thus, the direct Taylor-Cauchy transform is defined by Cauchy's integral, whereas its inverse is given in the form of a Taylor series, the summation of $w_{n,k}\lambda^n$.

The Laurent-Cauchy transform is another member of a general class of transforms. It is useful in the analysis of systems involving discrete processes, whereas the Taylor-Cauchy transform deals with continuous nonlinear processes. The direct Laurent-Cauchy transform is defined by (21), where the left-hand member represents symbolically the summation of $h_n\rho^{-n}$, which has the form of a Laurent series. On the other hand, the inverse transform defined by (22) takes the form of Cauchy's integral given in (14). Thus, not only are the two complex variables reciprocals of each other as defined in (3), the complex contour integral (1) defines the direct transform in the case of the Taylor-Cauchy transform, whereas the complex contour integral (14) defines the inverse transform in the case of the Laurent-Cauchy transform. In the Taylor-Cauchy transform method, $W^{(k)}(\lambda)$, the kth derivative of $W(\lambda)$, converges inside a circle. In the Laurent-Cauchy transform method, $H(\rho)$ converges outside a circle of radius R defined in connection with (16) and (17). Although both the Laurent-Cauchy and Taylor-Cauchy transforms belong to a general class of transforms, each has a realm of usefulness in the analysis of physical systems.

X. CONCLUSION AND DISCUSSION

This paper has presented some aspects of a discrete-to-continuous transform method for analyzing certain linear systems. Since the use of sequence functions reduces the labor in solving problems arising in the analysis of systems which are modulated in some manner, the Laurent-Cauchy transform is useful. In addition, if t is fixed, we can solve sum-difference equations and evaluate the sum of certain series which are $\mathfrak{L}_c$-transformable. Further, if n is considered as a discrete time variable, we can solve equations representing retarded feedback control systems such as a difference frequency AFC.[9] In the latter connection, if n is replaced by nT, where T is a sampling time, and the discrete variable h_n is taken to mean $h(nT)$, we see that (12) and (13) reduce to the Z-transform.[10–12] If the input to a given discrete system is random, the Laurent-Cauchy transform can be used in the transform-ensemble method in determining the response of the system statistically.[6]

XI. ACKNOWLEDGMENT

The authors wish to acknowledge the support extended them by the National Science Foundation in making these studies on nonlinear theory and related fields, and the encouragement of Dr. J. G. Brainerd. Thanks are also due to Dr. R. Weller and K. Lord of the Stromberg-Carlson Company.

TABLE I

LAURENT-CAUCHY TRANSFORMS

1) Operational Forms

h_n	$H(\rho)$
$C_1h_n \pm C_2g_n$	$C_1H(\rho) \pm C_2G(\rho)$
$\Delta h_n = h_{n+1} - h_n$	$(\rho-1)H(\rho)$
$\Delta^2 h_n = h_{n+2} - 2h_{n+1} + h_n$	$(\rho-1)^2H(\rho)$
$\Delta^k h_n$	$(\rho-1)^kH(\rho)$
$u_n = \begin{cases} 1; \text{ for } n \geq 0 \\ 0; \text{ otherwise} \end{cases}$	$\frac{\rho}{\rho-1}$
$\delta_n = \begin{cases} 1; \ n = 0 \\ 0: \ n \neq 0 \end{cases}$	1
δ_{n-k}	ρ^{-k}
n	$\frac{\rho}{(\rho-1)^2}$
n^2	$\frac{\rho(\rho+1)}{(\rho-1)^3}$
n^3	$\frac{\rho(\rho^2+4\rho+1)}{(\rho-1)^4}$
n^k	$(-1)^kD^k\left(\frac{\rho}{\rho-1}\right); D = \rho\frac{d}{d\rho}$
$a^{-n}h_n; \quad a > 0$	$H(a\rho)$
$a^n h_n$	$H\left(\frac{\rho}{a}\right)$
h_{n+k}	$\rho^kH(\rho) - \sum_{r=0} h_r\rho^{k-r}$
h_{n-k}	$\rho^{-k}H(\rho)$
$e^{an}h_n$	$H(e^{-a}\rho)$
$\sum_{k=0}^{n} h_kg_{n-k} = \sum_{k=0}^{n} g_kh_{n-k}$	$H(\rho)G(\rho)$
$\sum_{k=0}^{n} kh_kg_{n-k}$	$-H'(\rho)G(\rho)$
$\sum_{k=0} k^ah_kg_{n-k}$	$(-1)^aH^{(a)}(\rho)G(\rho)$
$\sum_{k=0}^{n} g_kg_{n-k}$	$G^2(\rho)$
$h_{n+k} = h_n$	$\frac{\sum_{r=0}^{k} h_r\rho^{k-r}}{\rho^k-1} = \frac{\sum_{r=0}^{k} h_r\rho^{-r}}{1-\rho^{-k}}$
$h_{n+k} = -h_n$	$\frac{\sum_{r=0}^{k} h_r\rho^{-r}}{1-\rho^{-k}}$
$-nh_n$	$\rho H'(\rho)$
$n(n-1)h_{n-1}$	$\rho H''(\rho)$
$-n(n-1)(n-2)h_{n-2}$	$\rho H'''(\rho)$
$(-1)^kn(n-1)'''(n-k+1)h_{n-k+1}$	$\rho H^{(k)}(\rho)$
h_{n+1}	$\rho H(\rho) - h_0\rho$
n^2h_n	$\rho^2H''(\rho) + \rho H'(\rho)$
$\sum_{k=0} h_ku_{n-k}$	$\frac{\rho H(\rho)}{\rho-1}$
$\sum_{k=0} k^2g_kg_{n-k}$	$G''(\rho)G(\rho)$
$\sum_{k=0} kg_kg_{n-k}$	$-G'(\rho)G(\rho)$
$-(n-1)h_{n-1}$	$H'(\rho)$
$(n-1)(n-2)h_{n-2}$	$H''(\rho)$
$-(n-1)(n-2)(n-3)h_{n-3}$	$H'''(\rho)$
$(-1)^k(n-1)\cdots(n-k)h_{n-k}$	$H^{(k)}(\rho)$

2) Functional Forms

h_n	$H(\rho)$
e^{-an}	$\frac{1}{1-e^{-a}\rho^{-1}}$
$1-e^{-an}$	$\frac{\rho^{-1}(1-e^{-a})}{(1-\rho^{-1})(1-e^{-a}\rho^{-1})}$
$\sin an$	$\frac{\rho\sin a}{\rho^2-2\rho\cos a+1}$
$\frac{1}{n!}$	$e^{1/\rho}$
$\cos an$	$\frac{1-\rho^{-1}\cos a}{1-(2\cos a)\rho^{-1}+\rho^{-2}}$
a^{bn}	$\frac{\rho}{\rho-ab}$
ah_n	$aH(\rho)$
h_{nr}	$H(\rho^{-r})$
$\sum_{r=0}^{k} a_r\rho_r^{\,n-1}$	$\frac{(\rho-q_0)\cdots(\rho-q_m)}{(\rho-\rho_0)\cdots(\rho-\rho_k)}$
where: a_r are the residues of the transform	
$-\frac{1}{n}$	$(\rho-1)+\log(\rho-1)$
e	$\frac{\epsilon^\rho}{\rho-1}$
$e^a a^n$	$\frac{e^\rho}{\rho-a}$
$a^n\sin a$	$\frac{\sin\rho}{\rho-a}$
$\frac{a^n\sin a\,(1-(-1)^n)}{\rho a^2}$	$\frac{\sin\rho}{\rho^2-a^2}$
$(\sin a)^{n-1}$	$\frac{1}{\rho-\sin a}$
$(\sin a)^n$	$\frac{\rho}{\rho-\sin a}$
$(\cos a)^{n-1}$	$\frac{1}{\rho-\cos a}$
$(\cos a)^n$	$\frac{\rho}{\rho-\cos a}$
$a^n\log a$	$\frac{\rho\log\rho}{\rho-a}$
$-n^3h_n$	$\rho^3H'''(\rho)+3\rho^2H''(\rho)$
$e^{-\alpha n}\sin an$	$\frac{\rho e^{-\alpha}\sin a}{\rho^2-2e^{-\alpha}\rho\cos a+1}$
$\frac{e^{-an}-e^{-bn}}{e^{-a}-e^{-b}}$	$\frac{\rho}{(\rho-e^{-a})(\rho-e^{-b})}$
$\frac{(-1)^{m-1}}{(m-1)!}\frac{\partial^{m-1}}{\partial a^{m-1}}(e^{-an})$	$\frac{(-1)^{m-1}}{(m-1)!}\frac{\partial^{m-1}}{\partial a^{m-1}}\frac{\rho}{(\rho-e^{-a})}$
$n^{[k]}h_n$	$(-1)^k\rho^k\frac{d^k}{d\rho^k}[H(\rho)]$
where: $n^{[k]} \equiv n(n-1)\cdots(n-k)$	
$\frac{(n+k)!}{(n-1)!}h_{n-k}$	$(-1)^k\rho^{2k}\frac{d^k}{d\rho^k}[H(\rho)]$
$a^{n-1}\log a$	$\frac{\log\rho}{\rho-a}$

TABLE I (Continued)

2) Functional Forms (Continued)

h_n	$H(\rho)$
$\frac{(n-1)(n-2)\cdots(n-k-1)}{(k-1)!}a^{n-k-1}$	$\frac{1}{(\rho-a)^k}$
$\frac{a^n}{a(a-b)}+\frac{b^n}{(b-a)b}$	$\frac{1}{(\rho-a)(\rho-b)}$
$\frac{a^n}{a-b}+\frac{b^n}{b-a}$	$\frac{\rho}{(\rho-a)(\rho-b)}$
$\frac{a^n}{2a^2}+\frac{(-a)^n}{2a^2}$	$\frac{1}{\rho^2-a^2}$
$\frac{a^n}{2a}+\frac{(-a)^n}{2a}$	$\frac{\rho}{\rho^2-a^2}$
$(n+1)h_{n+1}$	$-\rho^2H'(\rho)$
$n(n+1)h_n$	$\rho^2H''(\rho)$
nh_{n+1}	$-\rho H'(\rho)-H(\rho)-h_0$
$\frac{h_{n+2}}{n+1}$	$h_0\rho^2+h_1\rho\log\rho-\rho\int H(\rho)d\rho$
$\frac{h_{n+2}}{n+1};\begin{cases}h_0=0\\h_1=0\end{cases}$	$-\rho\int H(\rho)d\rho$
$\frac{1}{(n+1)!}$	$\rho e^{1/\rho}$

3) Theorems

a) Initial value theorem

$$\lim_{n\to\infty} h_n = \lim_{\rho\to\infty} H(\rho).$$

b) Final value theorem

$$\lim_{n\to 0} h_n = \lim_{\rho\to 1} (\rho-1)H(\rho).$$

c) Unit value theorem

Case I: $H(\rho)$ has no poles in the contour C

$$\sum_{n=0}^{\infty} h_n = \lim_{\rho\to 1} H(\rho).$$

Case II: $H(\rho)$ has poles inside the contour C

$$\sum_{n=0}^{\infty} h_n = \frac{1}{2\pi j}\int_C \frac{H(\rho)}{\rho-1}\,d\rho.$$

d) Summation Theorems

$$\sum_{n=0}^{\infty} f_n = \frac{1}{2\pi j}\int_C \frac{F(\rho)}{\rho(1-\rho)}\,d\rho$$

$$\sum_{n=0}^{k} f_n = \frac{1}{2\pi j}\int_C \frac{F(\rho)(1-\rho^{k+1})}{\rho(1-\rho)}\,d\rho$$

$$\sum_{n=0}^{\infty} y_nh_n = \frac{1}{2\pi j}\int_C \rho^{-1}Y(\rho)H(\rho^{-1})d\rho$$

$$\sum_{n=0}^{\infty} y_n^2 = \frac{1}{2\pi j}\int_C \rho^{-1}Y(\rho)Y(\rho^{-1})d\rho.$$

CORRECTION

J. J. Bussgang, P. Nesbeda, and H. Safran, authors of "A Unified Analysis of Range Performance of CW, Pulse and Pulse Doppler Radar," which appeared on pages 1753–1762 of the October, 1959, issue of PROCEEDINGS, have requested that the following corrections, resulting from an inquiry by M. Skolnik, be made to their paper.

In Case 3, on page 1756, a pulse Doppler radar was compared with a pulse radar of the same average power, antenna gain and noise figure. It was found incorrectly that the former type of radar had a detection range 80 per cent greater than the latter. The error which occurred was due to the fact that the conditions of this Case were not consistent with the earlier text.

Specifically, in the second column on page 1757, the last sentence before the subheading states: "For the pulse radar, N is the actual number of pulses." This is consistent with the earlier statement on page 1756, immediately following (6): "In (6) B_{IF} is assumed to match the pulse width"; *i.e.*, $B_{IF}\tau=1$.

However, our Case 3 is not consistent with this assumption, namely,

$$B_{\text{IF}}\tau = (5\times10^6)(2\times10^{-6}) = 10.$$

Thus each pulse is constituted of 10 independent samples and we should have taken

$$N = (\text{number of pulses})\times(B_{\text{IF}}\tau),$$

or, for Case 3,

$$N = 10\times10 = 100,\ \text{with } N = 100;$$

in Fig. 5, we now read

$$(R/R_0)_p = 1.14. \tag{35'}$$

Hence the over-all result should have been

$$(R)_d/(R)_p = \frac{(R/R_0)_d}{[(R/R_0)_p]\cdot[(R_0)_p/(R_0)_d]} = \frac{0.76}{1.14\times0.55} = 1.21$$

rather than $(R)_d/(R)_p=1.8$.

Thus in this particular Case, the pulse Doppler radar has 21 per cent more detection range.

Apart from noting this error, the authors wish to emphasize that it was not their intent to claim in this example that the pulse Doppler radar is superior in performance to the pulse radar under all circumstances. The purpose of the example was to demonstrate a method of comparison. Were a different set of parameters selected, the conclusions may well have been reversed. In particular, in this example the IF bandwidth was much wider than would be normally required and was quite unfavorable to a pulse radar.

Radio Frequency Scattering from the Surface of the Moon*

Several investigations of the lunar surface, using pulses which are short compared to lunar dimensions, have identified the marked "high-light" returned by quasispecular reflection from the central region of the lunar face.[1–5] Our observations, using a high-power, 400-mc radar show that the moon behaves not only as a smooth reflector but also as a diffuse scatterer. It is the purpose of this communication to show that weak, transient echoes are present from the entire lunar surface that is within view of the earth, provided that sufficient equipment sensitivity is employed.

Two radars, each equipped with a fully-steerable parabolic reflector, have been used in the course of these investigations and are described in Table I.

A typical intensity-modulated, range vs time display of the echoes observed with the more sensitive radar in Scotland is shown in Fig. 1. Transient echoes are detectable out to ranges corresponding to the limbs of the moon. The echoes appear to change range rapidly, a phenomenon which is presumably explainable by interference between energy packets arriving from the moon at the same time but having different Doppler shifts. A better indication of the manner in which received power falls off with distance is shown by the 15-second superposition of *A*-scope pulses shown in Fig. 2. A strong echo from the first 400 kilometers is the most prominent feature, followed by a linear decrease of echo energy[6] with range.

If each element of the lunar surface is assumed to scatter energy isotropically, *i.e.*, $P(\phi)=1$, where $P(\phi)$ = polar diagram of elementary scatterer and ϕ = angle with respect to the direction of specularly-reflected energy, then simple considerations show that the echo power as a function of range should decrease linearly as follows:

$$P_e \propto R\left(1-\frac{x}{R}\right)dx$$

TABLE I

Radar Parameters

	College, Alaska	Fraserburgh, Scotland
Antenna diameter	60 feet	142 feet
Antenna gain	36 db	43 db
Transmitter peak power	50 kw	130 kw
Frequency	398 mc	401 mc
Pulse length	1000 microseconds	300 microseconds
PRF	30 cps	30 cps
Receiver bandwidth	1 kc	6 kc
Polarization transmitted	Linear horizontal	Linear vertical
Received	Horizontal and vertical	Vertical

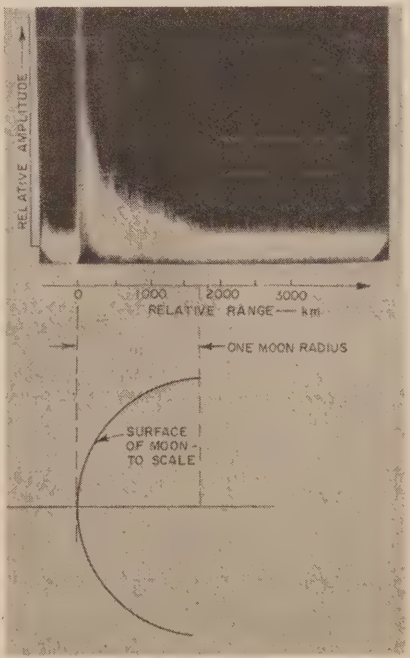

Fig. 2—Amplitude vs range display of lunar echoes with 15 seconds of integration at a pulse repetition frequency of 30 cps.

where

P_e = power reflected,
R = radius of the moon,
x = range measured from front face of the moon,
dx = increment of range.

However, if each element of the lunar surface is assumed to reflect according to a law

$$P(\phi)\propto\left(\frac{\sin\phi}{\phi}\right)^n,$$

then a fit to the initial sharp leading echo might be obtained by selecting an appropriate value for the unknown exponent n.

The echo shown in Fig. 2 shows evidence of both components being present. The two can be separated by fitting a straight line to the tail of the echo and considering the main leading edge to be superimposed on this linear variation. The results of this procedure yield an empirical scattering law of the following form,

$$P(\phi)\propto\left(\frac{\sin\phi}{\phi}\right)^{20\pm 6}+\frac{1}{10}.$$

where $-\pi<\phi<\pi$.

The discovery of this residual echo can be directly attributed to the use of an unusually sensitive radar. In earlier short-pulse experiments, this component was generally immersed in the receiver noise. Its presence is sufficient to explain the observed 20-db discrepancy[2] between the lunar equivalent cross-section values derived by short-pulse, and by continuous wave techniques. In the latter case, the weak component, because of its long time duration, is remarkably effective in contributing to the total echo energy.

[6] The receiver output amplitude shown in Fig. 2 was originally taken to be proportional to input power. Actually, the output is proportional neither to input power nor voltage but to some function between these limits.

The use of short pulses allows the moon to be divided into range increments which appear to the observer as a family of concentric rings (see Fig. 3). On the other hand, a property of a rotating sphere is that loci of constant Doppler shift appear to the observer as linear strips, each parallel to the instantaneous axis of rotation[7] (which can be calculated for the moon). By simultaneously recording both range and Doppler shift (on the order of a few cps at 400 mc), the lunar surface might be mapped with the present equipment without resorting to further resolution in angle.

Measurements of Lunar Reflectivity Using the Millstone Radar*

A new method[1] for mapping the source of radar echoes from distant rotating targets has been applied to lunar echoes obtained by the Millstone Radar of Massachusetts Institute of Technology's Lincoln Laboratory. In this method, an accurate spectral analysis of power density is carried out for each of many range intervals encompassing the extent of the returned signal in frequency and time. For a given apparent target rotation or libration with respect to the radar line of sight there is a proportional relation between the differential frequency displacement of the return and its location along an angular coordinate perpendicular to the instantaneous axis of libration.[2,3] A simultaneous determination of the range will thus fix the return as lying at the intersection of the appropriate range and frequency contour. In the case of a spherical body like the moon, the contours will take the form shown in Fig. 1. Viewed from the side, these contours form a simple rectangular grid bounded by the spherical surface of the moon. The presence of a two-fold ambiguity in the mapping of such data back to the lunar surface should be noted.

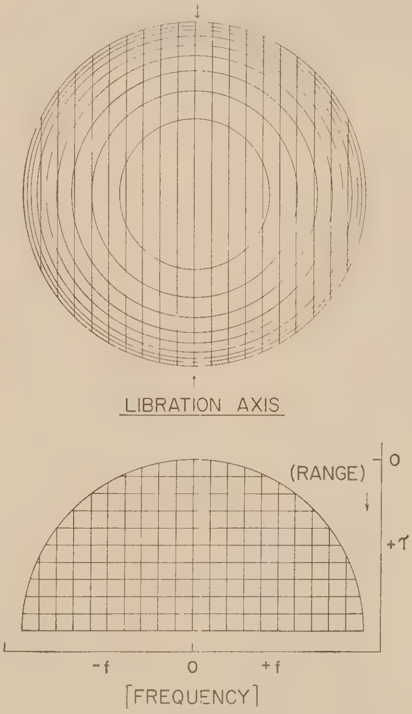

Fig. 1—Range-frequency contours for the moon as viewed from the earth. The Doppler shift arising from motion of the lunar center of mass has been removed.

By the use of a coherent train of short pulses, where the interpulse interval is chosen to be greater than the radar depth of lunar echoes, 11.6 msec, highly accurate frequency data have been obtained at no sacrifice in range resolution. Synthesis of all frequencies used in both transmitter and receiver from a common ultra-stable 1-mc/sec crystal oscillator ensured a maximum of stability. Measurements carried out at a time of exceptionally low lunar libration showed an over-all frequency stability of better than 5 parts in 10^{11} over the echo time of approximately 2.5 seconds. Digital recording of the returned signal waveform, in both amplitude and phase, allowed analysis at a later time with no loss in accuracy.

Fig. 2 shows a typical set of results obtained using the radar parameters listed in Table I. The format employed may be compared directly with Fig. 1. Each horizontal line displays in compressed form a Fourier analysis of the power density at a given range where the factor necessary to reduce the scale to a common maximum value is shown at the left. A scale factor threshold has been used to suppress noise on those traces devoid of echoes. Receiver and sky noise yields an average power of some 1 or 2 units on the scale shown, or some 50 db below the peak returned signal density. Range increments are in multiples of 500 μsec. The frequency resolution which results from the 9-second pulse train used is approximately 0.1 cps, yielding more than 100 elements transverse to the axis at times of maximum libration.

The qualitative features which are immediately obvious are: the presence of substantial echoes out to the limbs, the sharp bounds to the spectra set by the geometrical constraints of the moon's surface, and the concentration of signal near the upper and lower frequency limits at the longer delay. The latter effect is geometrical and results from the tangential intersection of range and frequency contours in those areas. Each run is processed and displayed automatically by the CG 24 digital computer located at the radar site. Since absolute frequency is preserved in the processing, an interesting byproduct of the experiment is the ability to determine the radial component of the lunar motion with a high degree of accuracy. During periods of low libration it appears possible to achieve a precision of approximately 0.02 cps or 2 parts in 10^6 of the observed Doppler frequency. A measurement of this accuracy may have application to geodesy and astronomy.[4]

The instantaneous axis of libration as viewed from moderate latitudes moves through an angle with respect to the selenographic polar axis which may be quite substantial over the course of a day. Therefore, it should be possible to resolve the remaining hemispheric ambiguity in the source of an echo at least for those cases where one hemisphere dominates. Three runs, spaced apart several minutes in time, have been made to study this effect. Preliminary analysis shows relatively little detailed correlation among the three. It is obvious that much patient work lies ahead before detailed correlation with optical photographs may be attempted. Perhaps of more immediate interest is the ability to select returns from areas of the lunar surface which appear to be optically uniform, and from these to build up a scattering law for unperturbed regions which may yield more precise information on the smoothness of the lunar "seas."

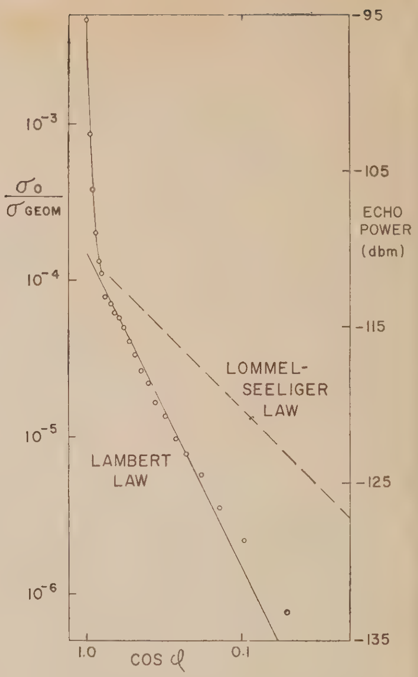

Fig. 3—Distribution of power in moon echoes plotted as a function of the cosine of the angle of incidence to the surface.

TABLE I
RADAR PARAMETERS

Transmitted frequency	440.182 mc
Antenna half-power (one-way) beamwidth	2.1 degrees
Antenna gain (above isotropic radiator)	37 db
Over-all system noise temperature	290°K
Polarization transmitted	right circular
Polarization received	left circular
Peak transmitted power	2.1 megw
Transmitted pulse length	500 μsec
Interpulse period	29.90 msec (exactly)
Pulse repetition rate	33.4448 per second (approx.)
Length of coherent pulse train	8.97 seconds
Sampling interval	500 μsec

As a corollary to the studies above, a measurement of mean total power as a function of range was undertaken. In order to smooth out short term fluctuations, integration was carried out for 16 minutes, including some 24,000 pulses at each 500-μsec range increment. All other parameters were as shown in Table I. Results are plotted in Fig. 3 as received power vs the cosine of the angle of incidence (with respect to the normal) to the lunar surface. Following the decay of the initial specular component, an important amount of diffuse reflection is evident which obeys a Lambert-type law, except for a small amount of limb brightening at extreme ranges. A similar brightening of the extreme limb has been observed optically.[5] The specular and diffuse contributions become equal at a delay of approximately 2 msec from the leading edge of the echo. At the left of the plot is shown the ratio between the radar cross section equivalent to the observed power and the full projected lunar area. For fully specular reflection from a perfectly conducting sphere, this ratio should equal unity at normal incidence and zero elsewhere.[6] Carrying out the integration under the curve yields a ratio between total radar and projected geometric cross section of only 0.01. The discrepancy between this and the higher values obtained by other workers[7] using long pulses or CW is unexplainable and will be a subject of future study. A comparison of the relative amounts of specular and diffuse reflection indicates that an average of about 10 per cent of the lunar surface is sufficiently rough at this frequency to exhibit Lambert scattering.

Without the invaluable aid of J. C. Henry, L. G. Kraft and G. Hyde, it would have been impossible to carry out these experiments in so short a time. Much gratitude is due Dr. P. Green for his suggestions and interest in this work.

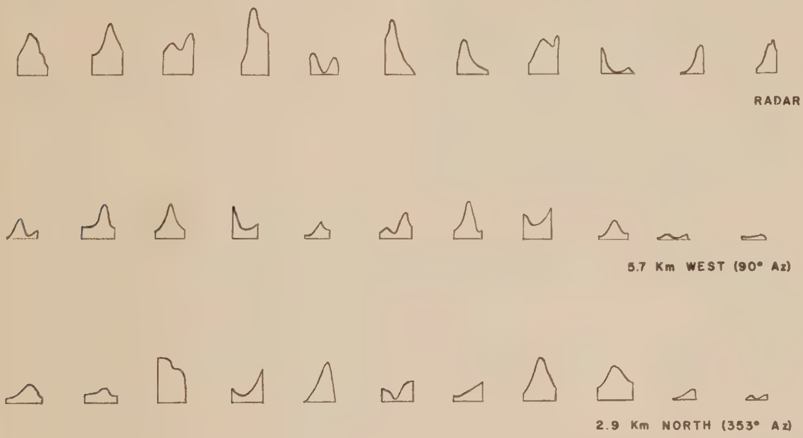

Fig. 1—Echoes from the moon on 106.1 mc, showing uncorrelated fluctuations at separated receivers, on January 11, 1958, at 0500–0501 PST, when the moon was near upper culmination. (Azimuth, 177°; elevation, 47°.)

absolute range,[6] and pulse broadening,[7–9] have been described by previous authors. This communication describes an attempt to measure the size of the patches of energy reflected onto the earth's surface and their possible velocities of motion along the earth's surface.

The moon, located in the broad beam of the transmitter, can be regarded as an irregularly-illuminated aperture having an irregular phase distribution. Thus, the moon may behave as an antenna having a complicated radiation pattern but having a narrowest lobe size given by the effective "width" of the lunar aperture. Thus, the minimum size of each of these patches is dependent upon the maximum subtended angle of the effective reflecting portion of the lunar surface.

In conjunction with the 106.1-mc radar employed by Stanford Research Institute for lunar echo studies, two partially mobile antennas, receivers, and recorders were assembled for use as remote receiving stations. (See Table I.) The antennas were directed at the moon approximately every 15 minutes using precomputed values of azimuth and elevation. Each of the three sites was equipped with a frequency-converter, Collins 51J4 receiver (bandwidth of approximately 200 cps) and a pen-chart (Brush) recorder capable of following the fastest variations of the libration-caused lunar echo fading. The transmitter was turned on (CW) for about 2.4 seconds and repeated every 5.1 seconds. With this timing, the echo from the moon began to return shortly after the transmitter pulse had ended, giving a useful received signal 40 per cent of the total period

Typical results from the first test are shown in Fig. 1. Correlation between these traces is less than 0.02. In April, 1958, the bus was moved to a convenient location approximately bisecting the line between the truck and the radar. Again, the results were largely uncorrelated. For the closest spacing used (1.15 kilometers north-south or 0.8 km projected) and after compensating for gain changes during the runs, the best correlation that could be achieved was 0.26. A search was made for similar amplitude fluctuation patterns shifted in time, in hopes of establishing a westward drift because of the earth's eastward motion. No pattern drift was found, possibly because the transmitter is not fixed with respect to the moon.

This result implies that much, if not all, of the lunar surface is effective in echoing a man-made signal. More definitive results would result, of course, using short-pulse experiments. For communication via the moon, this result implies that a diversity distance of about one kilometer projected at right angles to the radio ray is certainly sufficient spacing to achieve diversity reception.

The research was made possible through the initiative of R. L. Leadabrand and through the willing efforts and long hours of more than a dozen assistants within the laboratory.

Noise Figure of Tunnel Diode Mixer*

An analysis has been made of the noise figure of a tunnel diode used as a mixer. The assumptions made were 1) the diode sees a short circuit at the image frequency, 2) the only source of noise in the diode is the shot noise associated with the tunnel current, 3) the series resistance of the diode and the losses of the input and output tuned circuits are negligible, and 4) the diode capacitance is constant. Because of the second assumption, consideration is limited to that portion of the i–v characteristic of the diode extending from reverse voltages up to, or somewhat beyond, the point of maximum negative conductance. In particular, the valley of the i–v characteristic is excluded from consideration because considerable excess $1/f$-type noise[1] has been observed in this region and this type of noise is not taken into account in the analysis.

Since the conductance of a tunnel diode can assume negative values, the possibility of a conversion gain greater than unity may be anticipated. The midband conversion power gain of a nonlinear resistance type of diode, defined as the ratio of IF output power to the power available from the RF source is

$$G = \frac{4r_1r_2g_1^2}{[(1+g_0r_1)(1+g_0r_2) - g_1^2r_1r_2]^2}. \quad (1)$$

In (1), r_1 and r_2 are the resistances seen by the diode at RF and IF, respectively, g_0 is the average conductance of the diode over the local oscillator cycle, and g_1 is the conversion conductance of the diode. The values of g_0 and g_1 are obtained from the Fourier series representation of the instantaneous incremental conductance g of the diode considered as a function of the local oscillator phase θ. Thus

$$g(\theta) = g_0 + 2g_1 \cos\theta + 2g_2 \cos 2\theta + \cdots. \quad (2)$$

If $g(\theta)$ is restricted to non-negative values then $0 \leq |g_1| \leq g_0$ and the maximum possible value of G for positive r_1 and r_2 is unity.

---

* Received by the IRE, January 22, 1960.

[1] T. Yajima and L. Esaki, "Excess noise in narrow germanium *p-n* junctions," *J. Phys. Soc. Japan*, vol. 13, pp. 1281–1287; November, 1958.

However, if $g(\theta)$ is free to assume negative values, then $g_0 < |g_1|$ is possible and the conversion gain cannot only exceed unity, but will become infinite for

$$r_2 = r_{2c} = \frac{1 + g_0 r_1}{g_1^2 r_1 - g_0(1 + g_0 r_1)}. \tag{3}$$

It can be shown that for stable operation the quantities $(1+g_0r_1)$ and $(1+g_0r_2)$ must both be positive or both negative. Assuming that both are positive, the condition that r_{2c} be positive is that

$$\gamma = \frac{|g_1| r_1}{1 + g_0 r_1} > \frac{g_0}{|g_1|} = \alpha. \tag{4}$$

For values of r_2 slightly below r_{2c}, the mixer gain is similar to that of a negative resistance amplifier; *i.e.*, the product of voltage gain and bandwidth is constant.

The noise figure of the tunnel diode mixer is

$$F = 1 + \frac{q(I_{0f} + I_{0r})}{2kT_1|g_1|} \frac{1 + \gamma^2 \pm 2K\gamma}{\gamma(1 - \alpha\gamma)} + \frac{1}{\gamma(1 - \alpha\gamma)} \frac{1}{|g_1| r_2} \frac{T_2}{T_1}. \tag{5}$$

$$\gamma_{\text{opt}} = \frac{\Big\} \alpha^2 \left(1 - \frac{\alpha}{M}\right)^2 + \left(1 - \frac{\alpha}{M}\right)\left[1 - \alpha\left(2K - \frac{1}{M}\right)\right]\Big\{^{1/2} - \alpha\left(1 - \frac{\alpha}{M}\right)}{1 - \alpha\left(2K - \frac{1}{M}\right)} \tag{9}$$

In (5)

$$K = -\frac{I_{1f} + I_{1r}}{I_{0f} + I_{0r}},$$

T_1 and T_2 are the temperatures of r_1 and r_2, respectively, q is the electronic charge, k is Boltzmann's constant, and the ± sign is to be taken as positive or negative according as g_1 is positive or negative. The quantities I_{0f} and I_{1f} denote the dc and fundamental components of the forward component of the tunnel current as defined by the Fourier series

$$i_f(\theta) = I_{0f} + 2I_{1f}\cos\theta + 2I_{2f}\cos 2\theta + \cdots. \tag{6}$$

Similarly I_{0r} and I_{1r} are the dc and fundamental components of the reverse component i_r of the tunnel current. The net tunnel current that is measurable is $i = i_f - i_r$. To separate i into i_f and i_r, the relations,

$$i_f = \frac{i}{1 - \exp(-qv/kT)},$$
$$i_r = i_f \exp(-qv/kT), \tag{7}$$

may be used. These relations can be derived from the theoretical expression for the tunnel current given in Esaki.[2] In (5) the first term represents thermal noise associated with the resistor r_1, the second term represents shot noise of the diode and the third term the thermal noise associated with r_2.

The derivation of (5) is similar to the derivation of the noise figure of a diode mixer given in Strutt,[3] except that the mean square shot noise at any point in the local oscillator cycle is set equal to $2q(i_r + i_f)\Delta f$ instead of $4kT_c g\Delta f$ as in (5) of Strutt.[3]

According to (5) of this note, the larger r_2 the better the noise figure of the mixer. However, the mixer conversion gain is more critically dependent on r_2 and high conversion gain is desirable to minimize the over-all noise figure of the system. In the absence of specific informarion concerning the noise figure of the IF amplifier, it appears reasonable to choose

$$r_2 \cong r_{2c} = \frac{1}{|g_1|(\gamma - \alpha)}. \tag{8}$$

For this choise of r_2, F has a minimum for $\gamma = \gamma_{\text{opt}}$ where

and

$$M = \frac{q(I_{0f} + I_{0r})}{2kT_2|g_1|}. \tag{10}$$

The above results were used to calculate the noise figure as a mixer of a G.E. ZJ56 germanium tunnel diode. The calculation was made for various values of bias and local oscillator drive on the assumption that the local oscillator voltage across the diode is sinusoidal. The best value obtained for the noise figure was 8.3 db for a forward bias of 100 mv and a peak local oscillator voltage of 90 mv. For this set of operating conditions $g_0 = +0.0029$ mho, $g_1 = -0.0069$ mho, $I_0 = 0.924$ ma, $I_1 = -0.346$ ma, $r_{1\,\text{opt}} = 135$ ohms and $r_{2c} = 600$ ohms. By way of comparison, the same diode used as a negative-resistance amplifier has a noise figure of about 5 db. The noise figure as a mixer is thus poorer than the noise figure as an amplifier. This result is to be expected unless more effective use can be made of "noise compensation" in the mixer.[4] Unfortunately, to obtain significant noise compensation, Class C operation of the diode is required and this mode of operation is not possible for the tunnel diode.

Effect of External Base and Emitter Resistors on Noise Figure*

Neilsen[1] has shown that the noise figure of a transistor in the common-emitter configuration is

$$F = 1 + \frac{r_b' + \frac{r_e}{2}}{R_g} + \frac{(1 - \alpha_0)\left[1 + \left(\frac{f}{\sqrt{1 - \alpha_0} f_\alpha}\right)^2\right](r_b' + r_e + R_g)^2}{2\alpha_0 r_e R_g}, \tag{1}$$

where R_g is the source resistance. The value of R_g for which F is minimum is

$$R_{gm} = \sqrt{\frac{2\alpha_0 r_e\left(r_b' + \frac{r_e}{2}\right)}{(1-\alpha_0)\left[1 + \left(\frac{f}{\sqrt{1 - \alpha_0} f_\alpha}\right)^2\right]} \cdots + (r_b' + r_e)^2}. \tag{2}$$

These expressions neglect both excess $(1/f)$ noise in the transistor and the noise contribution of any external elements such as bias resistors.

Middlebrook[2] has derived expressions for the noise figure and optimum source resistance of a common-emitter transistor amplifier containing external base and emitter resistors, but these expressions do not account for the effect of the transistor input resistance.

It is possible to derive expressions for the noise figure and optimum source resistance of an amplifier which neglect only excess noise in the transistor. Fig. 1 shows an approximate equivalent circuit of a common-emitter amplifier. R_1 is a base biasing resistor and R_2 is an unbypassed emitter resistor. The noise figure of this circuit is

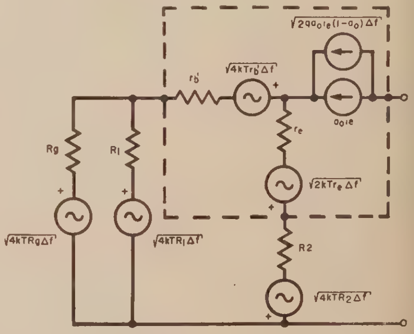

Fig. 1—Equivalent circuit of a common-emitter amplifier containing noise sources.

$$F' = 1 + \frac{R_g}{R_1} + \left(1 + \frac{R_g}{R_1}\right)^2 \left[\frac{r_b' + \frac{r_e}{2} + R_2}{R_g} + \frac{(1 - \alpha_0)(r_{b'} + r_e + R_2 + R_p)^2}{2\alpha_0 re R_g}\right], \tag{3}$$

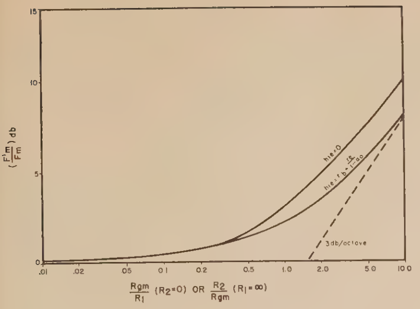

Fig. 2—Increase in minimum noise figure caused by R_1 or R_2.

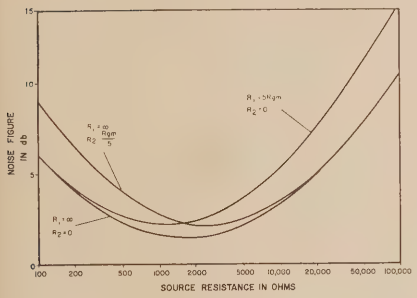

Fig. 3—Variation of noise figure vs source resistance with R_1 and R_2 as parameters.

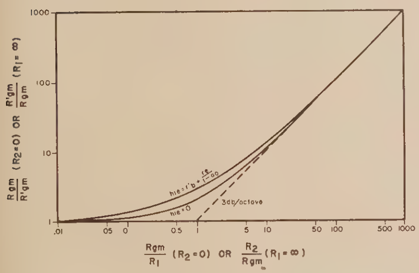

Fig. 4—Optimum source resistance R_{gm}' as a function of R_1 or R_2.

where R_p is $(R_1R_g)/(R_1+R_g)$. In (3), it is assumed that $f \ll \sqrt{1-\alpha_0}\, f\alpha$.

The amplifier noise figure (F') has a minimum value for $R_g = R_{gm}'$, where R_{gm}' is related to R_{gm} by

$$\frac{R_{gm}}{R_{gm}'} = \left[\frac{1+\dfrac{R_{gm}^2+R_2(2h_{ie}+R_2)}{R_1^2}+\dfrac{2(h_{ie}+R_2)}{R_1}}{1+\left(\dfrac{R_2}{R_{gm}}\right)^2+\dfrac{2h_{ie}R_2}{R_{gm}^2}}\right]^{1/2}. \quad (4)$$

In (4), $h_{ie} = r_b' + r_e/(1-\alpha_0)$ and is the low-frequency, common-emitter input resistance of the transistor.

Eq. (3) shows that the presence of R_1 and R_2 increases the amplifier noise figure. In Fig. 2, the ratio of the minimum amplifier noise figure to the minimum transistor noise figure, in db, is plotted vs R_{gm}/R_1 and R_2/R_{gm}, for a typical transistor having the following parameters:

$$r_e = 50 \text{ ohms}$$
$$r_b' = 250 \text{ ohms}$$
$$\alpha_0 = 0.990.$$

The ratio F_m'/F_m, in db, approaches an asymptote of 3 db per octave. Note that the effect of the input resistance is to shift the "break point" of the curve from a normalized value of unity to some greater value. The input resistance, therefore, reduces the degradation of the noise figure caused by R_1 and R_2.

Fig. 3 shows the variation of amplifier noise figure vs source resistance for typical values of R_1 and R_2. In accord with (4), it is seen that a finite value of R_1 decreases the value of the optimum source resistance, while a nonzero value of R_2 increases the optimum source resistance. Fig. 4 shows the behavior of the optimum source resistance with variation in R_1 and R_2. At low values of R_1, R_{gm}' approaches R_1, while at high values of R_2, R_{gm}' approaches R_2. The input resistance accentuates the effect of a given R_1 or R_2 on the optimum source resistance.

A Ferromagnetic Amplifier Using Longitudinal Pumping*

A number of ferromagnetic parametric amplifiers using a transverse RF magnetic field as the pump have been proposed and investigated.[1–4] However, for various reasons none of these amplifiers has resulted in a practical device. It now appears that a ferromagnetic amplifier can be built using longitudinal pumping (RF magnetic field parallel to the dc magnetic field). Early experimental results on this type of amplifier have given a CW gain of 25 db with a signal frequency in the 4000-mc range using an X-band pump power of less than a watt.

The amplifier consists of a sample of ferromagnetic material mounted in a cavity, resonant at the pump frequency, with a transmission line to couple energy into the sample at the signal frequency. Resonances at the signal and idler frequencies are provided by normal modes of the ferromagnetic material.[5] The normal modes of a spheroidal sample of ferromagnetic material have been obtained by Walker,[6] and a straightforward calculation shows that certain pairs of these modes can be pumped parametrically by an RF field in the longitudinal direction. The calculation indicates which pairs of modes can be pumped and their respective thresholds for oscillation. The restriction on the pairs of modes which can be pumped comes from the form of the magnetostatic potentials as obtained by Walker and can be expressed as a set of selection rules. The magnetic field must, of course, be adjusted so that the resonant frequencies of the modes add up to the pumping frequency.

The ferromagnetic sample was a sphere of single-crystal yttrium iron garnet 0.043 inches in diameter mounted in a half-wave X-band cavity at a point of maximum RF magnetic field and spaced 0.075 inches from the cavity wall. The sphere, which had a linewidth of 0.40 oersteds, was furnished by Spencer and LeCraw. A loop of wire was threaded through holes in the wall of the cavity and around the sphere in a plane containing the dc and RF magnetic fields, to provide coupling from a coaxial line into the sample. A measure of the strength of coupling between the loop and the sample modes was obtained by observing the reflection of a signal in the coaxial line in the absence of the pump: 64 resonances were readily resolved as the dc magnetic field was varied. CW pump excitation of the cavity at 9196 mc was then applied at a power level of 500 mw. At each of a number of dc field values, a pair of modes was observed to undergo steady oscillation. Amplification was obtained by setting the dc field to single out one such pair and by reducing the pump power. Amplifier operation for a typical pair of modes is illustrated in Fig. 1, which shows reflection by the sphere of a swept frequency signal in the coaxial line without pumping [Fig. 1(a)] and with pumping [Fig. 1(b)]. Note that a number of absorptions due to sample modes appear in Fig. 1(a); the notch in the center is due to a wavemeter at 4598 mc (half the pumping frequency). The modes at 4626 and 4570

mc have been identified as the 310 mode and the $3\bar{1}1$ mode (Walker's notation).[6] It may be observed that they satisfy the frequency relation for parametric pumping. They also satisfy the selection rules referred to above. These are the modes which are amplifying in Fig. 1(b). Fig. 2 also shows the energy reflected from the sphere, but on an expanded frequency scale centered about the 310 mode. The gain measurement was performed using a signal generator, the amplifier, and a detector on the arms of a three-port circulator. The detector output was compared with that obtained when a shorting plate was substituted in the amplifier arm, showing a gain of 25 db. Work is still in a very early experimental stage; measurement of bandwidth, noise figure, and other characteristics is proceeding.

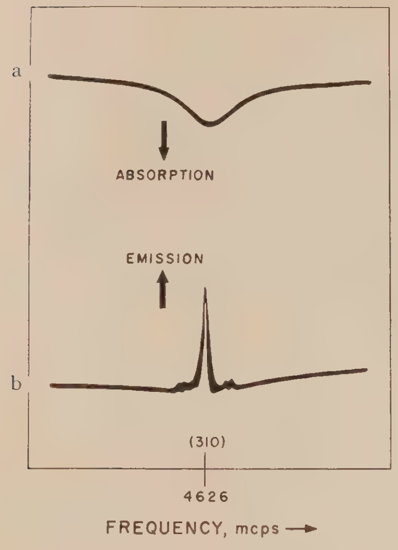

Fig. 2—Walker mode resonance (310) on an expanded scale. (a) Without pumping. (b) With pumping.

This amplifier appears capable of fulfilling the expectations which have made the ferromagnetic parametric amplifier principle attractive: namely, it operates at room temperature but being a magnetic device can also, of course, be operated at low temperatures; it is not susceptible to burnout or long-term saturation caused by high-power transients; and it is capable of being used up to very high signal frequencies. In the style of operation reported here, use at high frequencies ought to present no special difficulties; this amplifier also exhibits the advantages of low pump power and lower dc magnetic field than required in some other proposals.

The investigation of longitudinal pumping which led to this new type of amplifier was stimulated by the work of Schlömann, *et al.*,[7] on the theory of spin-wave excitation, and the studies of LeCraw and Spencer.[8] Spencer and LeCraw have been very generous in devoting time to discussions, offering suggestions, and providing experimental assistance. The author would like to thank J. A. Weiss for many helpful and stimulating discussions. V. Czarniewski has contributed very skillful technical assistance.

Parametric Phase Distortionless *L*-Band Limiter*

A. E. Siegman[1] has predicted, from theoretical considerations, that a parametric device could be made to limit at *pump* frequency, without phase distortion. Such a limiter, operating at *L*-band, has successfully been developed in our laboratory. Over 30 db of dynamic limiting has been observed at 1000 mc, with the parametric limiter operating in the degenerate mode. Phase distortion measurements have been made over a 16-db range of limiting. The phase distortion was observed to be less than ±2°, which was the accuracy of the measurements.

Fig. 1 is a schematic of the limiter. Three shorted coaxial transmission line cavities (pump and two idlers) are joined at a tee. A Microwave Associates MA460A VARACTOR is placed in shunt with all three cavities at their junction. Provisions are made for biasing the VARACTOR over the range ±4 volts, with suitable RF bypassing. Two loops couple pump signal in and limited pump signal out of the pump arm. Additional loops are provided in the idler arms for monitoring idler frequencies.

Siegman did not describe an actual device; however, he did suggest, in an example, that the pump cavity be designed to resonate in two degenerate modes at pump frequency. Coupling between modes would be afforded by the nonlinear element. Pump signal would be coupled into one mode, while output signal would be coupled to the second. Limiting occurs when the device breaks into oscillation, causing the nonlinear coupling between the two degenerate modes to "clamp." It appears, from our experience, that such coupled degenerate modes are not a necessary feature for the device to function. In our device, the dimensions of the coaxial pump cavity are such that all higher TE and TM modes are well below cutoff. Both input and output loops couple to the TEM mode, for which no degeneracy exists.

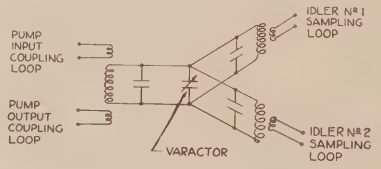

Fig. 1—Schematic of limiter.

Tests of the dynamic limiting capabilities were made at 1000 mc, using $3\frac{1}{2}$-μsec (half amplitude width) pseudo-Gaussian RF pulses. Photographs taken using a high-speed *X-Y* oscilloscope are shown in Fig. 2. In Fig. 2(a), a dual trace is shown of the pseudo-Gaussian input pulse and of the limited output pulse. The output pulse is shown again in Fig. 2(b), amplified to show greater detail. Fig. 2(c) is an *X-Y* presentation showing output vs input. The 45° trace is a plot of input vs input, provided for comparison. Fig. 2(d) is again an *X-Y* presentation of output vs input; the output signal has been amplified to show greater detail of the limiting action. The limiter was operat-

ing in the degenerate mode (both idler frequencies at one-half pump frequency). Average input power was 280 mw. Peak input power was in excess of 15 watts.

Phase distortion measurements were conducted under pulsed conditions at 1000 mc, with the limiter operating in the degenerate mode. It is essential, in such measurements, that the phase of the input signal to the limiter does not vary as its amplitude is varied. In other words, the device used to vary input signal amplitude must not in itself introduce phase distortion. Several variable attenuators were found to be lacking in this respect. The problem was solved in the manner illustrated in Fig. 3.

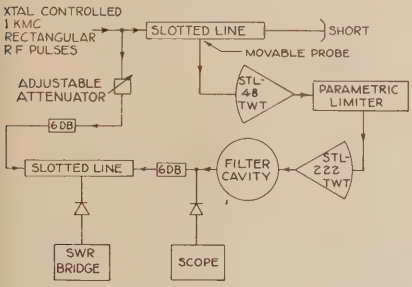

Fig. 3—Experimental setup for phase distortion measurement.

A crystal-controlled source of rectangular pulses at 1000 mc was fed into a shorted slotted line, creating an infinite VSWR on that line. A well-known property of such a standing-wave pattern is that the phase of the RF voltage between adjacent minima is independent of distance along the line. Thus, by moving a probe back and forth between a minimum and a maximum of such a standing-wave pattern, the RF output from the probe could be made to vary over a wide range, the phase remaining constant. It is necessary that the probe be only lightly coupled to the slotted line; otherwise the perturbation of fields introduced by the probe will destroy the above relationship. Therefore, the insertion loss of this amplitude varying device is necessarily high.

The high insertion loss was overcome by amplifying the signal out of the probe to a sufficient level to drive the limiter. A Sperry STL-48 TWT was used for this purpose. This is a high-power (200-watt CW) TWT, chosen so that the power levels at which our phase measurements were to be made were well down in the small signal region, to avoid amplitude-to-phase conversion introduced by the TWT itself. A separate check of this phase distortion due to the TWT was made; over the amplitude range used, it was less than ±2°, which was the accuracy of our measurement.

The limited output was amplified using a Sperry STL-222 TWT, passed through a cavity filter tuned to pump frequency, then through 6 db of lossy cable to one end of a slotted line. A sample of the crystal-controlled RF drive was fed through 6 db of lossy cable to the other end of the slotted line, as phase reference signal. By adjustment of the amplitude of the phase reference signal, an infinite VSWR was established on that slotted line. Any phase shift in the limited output signal caused a corresponding shift in the position of the minimum of standing-wave pattern, which could be correlated directly to phase shift in degrees. Over a 16-db range of limiting, the phase shift was observed to be less than ±2°, the accuracy of our measurement.

It will be noted that the block diagram of Fig. 3 includes a filter cavity, tuned to pump frequency, in the output line of the limiter. Its purpose was to filter out any idler frequencies which might be coupled to the output loop. We found that the limiter worked better when this filter was present. It will also be noted that this filter is isolated from the limiter by a nonreciprocal circuit element (the STL-222 TWT). Thus, the limiter saw an impedance of 50 ohms. We found that this order of component placement worked best. When the filter cavity and the TWT were reversed in position, some "ringing" occurred on the output pulse. This ringing was affected by filter cavity tuning.

The operation of the limiter was observed to be critically dependent upon the tuning adjustment of all three cavities, as well as upon the bias adjustment. There appeared to be a broad combination of idler frequencies F_1 and F_2 satisfying the relationship

$$F_1 + F_2 = F_p$$

such that limiting would occur. However, it was found that the best limiting action occurred when the limiter operated in the degenerate mode, where

$$F_1 = F_2 = F_p/2.$$

The authors wish to express their appreciation to J. R. Ashley, who suggested the experimental technique used for monitoring phase distortion.

The Diode-Loaded Helix as a Microwave Amplifier*

Earlier work on traveling-wave parametric structures has included cavity devices and transmission line devices.[1] Theoretical and some experimental work has been done at these Laboratories with a diode-loaded coaxial line.[2]

More recently, exploratory work was done with an *S*-band helix-loaded with *p-n* junction diodes, in an attempt to develop a four-terminal microwave amplifier with broad-band properties. In addition to broad-band behavior, the helix structure is directional and the signal and pump sources can be isolated by the helix. It is fairly easy to couple to the helix and this can be done at any point along it if, for instance, distributed pump coupling is desired. *A priori*, a large variation in amount and kind of loading is possible. Experience with the loaded coaxial line has indicated that a small loading per unit length, distributed over the structure, is desirable.

The helix is shown in Fig. 1. It is of silver-plated tungsten wire (20-mils diameter). Designed for *S*-band operation, it is 6 inches long, has a 0.276-inch mean diameter, and has approximately 13 turns per inch. The diodes,[3] mounted between turns of the coil, are of germanium, alloyed-diffused, and have the following characteristics:

Capacitance (−1 volt)	0.2–1 μμf,
Series resistance	2–15 ohms,
Cutoff frequency (nominal)	20–100 kmc.

They were assembled in ceramic cylinders about 0.1 inch in diameter, of axial dimension quite close to that of the interturn spacing of the helix.

The test apparatus is shown schematically in Fig. 2. It was found that the position of each diode on the helix was critical, as was the pump power and pump frequency. No general relations among pump frequency,

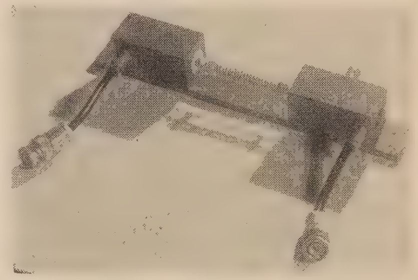

Fig. 1—The helix.

Heilmeier, "An analysis of parametric amplification in periodically loaded transmission lines," *RCA Rev.*, vol. 20, pp. 442–454, September, 1959; also, "Research and Development on Parametric Amplifiers," AF Cambridge Res. Ctr., Cambridge, Mass., 2nd Quart. Rept., Contract AF19(604)-4980, June 30, 1959.

[3] Thanks are due C. W. Mueller's Device Group, in these Laboratories, for a supply of developmental diodes.

signal frequency and diode position and characteristics were observed.

Typical operating data are shown in Table I.

TABLE I

Signal frequency	2800 mc
Pump frequency	3800 mc
Number of diodes	2
Pump power	60 mw
Unloaded helix insertion loss	−6 db
Net power gain	26 db
Voltage gain-bandwidth	30 mc
Noise figure	5–7 db

It can be seen that the bandwidth is quite low, presumably because of the loading introduced by the diodes. The broad-band properties are retained to the extent that, at least for some diode arrangements, the structure can be tuned by varying the pump frequency and power. Thus, for a pump frequency variation of 100 mc, the signal frequency has been moved through an 80-mc range.

A High Field Effect Two-Terminal Oscillator*

As early as 1953,[1] charge multiplication in reverse biased *p-n* junctions was reported. A rather rigorous treatment by McKay[2] in 1954 prompted additional work by Eber and Miller,[3] Kidd, *et al.*,[4] and many more. Recently Gunn[5] and Yamaguchi and Hammakawa[6] have discussed the negative resistance properties associated with avalanche multiplication. The purpose of this note is to indicate the application of this phenomenon to sinusoidal oscillators using readily available solid-state devices.

It is interesting to note that this breakdown effect can be observed at the collector-base junction of most low-power transistors. A typical volt ampere characteristic for a 2N147 (linear gradient) unit is shown in Fig. 1. Characteristics for both step and linear gradient junctions have been obtained and are quite similar in nature.

The requirement of a negative resistance device in two-terminal oscillators is known,[7] and in an effort to exploit the high field effect more fully, the oscillator of Fig. 2 was constructed. The equivalent of Fig. 2 is shown in Fig. 3, where $-R$ is the average negative resistance value of the junction over the operating range.

Minimum Negative Resistance Requirement

From elementary circuit theory,

$$E_{0(s)} = \frac{sC_1^2[e_1(0^+) - e_2(0^+)] - (g_e + sC_1)[C_1e_1(0^+) - (C + C_1)e_2(0^+)]}{(g_e + sC_1)\left[sC - sC_1 + \frac{1}{R_1} - \frac{1}{R_1^2\left(\frac{1}{sL} + \frac{1}{R_1}\right)}\right] - s^2C_1^2}. \quad (1)$$

From (1) the characteristic equation is

$$s^3LC_1(C_e - C_1) + s^2[Lg_eC_e + R_1C_1C_e - C_1^2R_1] + s[R_1g_eC_e + C_1] + g_e = 0 \quad (2)$$

where

$$g_e = \frac{1}{R_L} - \frac{1}{R}$$

$$C_e = C - C_1.$$

Under the linearized assumptions, a minimum condition for oscillation requires that the conjugate roots of (2) be purely imaginary. Thus (2) is of the form

$$(s + a)(s^2 + \omega^2) = 0 \quad (3)$$

or

$$s^3 + as^2 + \omega^2 s + a\omega^2 = 0. \quad (4)$$

Comparing (4) and (2) yields

$$\omega = \sqrt{\frac{R_1g_eC_e + C_1}{LC_1(C_e - C_1)}}, \quad (5)$$

or a minimum average value of negative resistance is found as

$$|-R| \geqq \frac{R_LR_1(C - C_1)}{R_1(C - C_1) - R_L\omega^2LC_1(C - 2C_1) + R_LC_1}. \quad (6)$$

For the oscillator circuit of Fig. 2, $\omega = 52{,}300$ rad/sec, and

$$|-R| \geqq 1.29 \text{ ohms}.$$

Maximum Negative Resistance Requirement

Assuming $C_1 = C$ and $\omega_{ar}^2 \cong 1/(2CL)$, the Thevenin antiresonant impedance at the *p-n* junction terminals is

$$R_{ar} = \frac{4R_1R_LL}{4R_1L + R_LL + 2R_LR_1^2C}. \quad (7)$$

To satisfy the requirement that the average ac power dissipated by the load resistance and tank circuit be supplied by the negative resistance device places an upper limit on the average value of the negative resistance as

$$|-R| \leqq R_{ar}. \quad (8)$$

For the circuit of Fig. 2,

$$|-R| \leqq 143 \text{ ohms}.$$

Observed waveforms (Fig. 4) indicate that a very low distortion signal may be developed.

A difficulty arises, however, since biasing the device in the negative resistance region causes rather large quiescent currents to flow through the narrow base region. The junction temperature rises, which quite abruptly results in the deterioration of oscillator performance.

In addition to work done with collector-base junctions, an investigation has been

Generating a Rotating Polarization*

By relatively simple means, it is possible to generate an arbitrarily-polarized wave whose polarization can be caused to rotate at virtually any desired angular rate. It is well known that any polarized wave can be resolved into components of right- and left-handed circular polarizations, or that any polarization can be constructed from appropriate combination of two oppositely sensed circularly polarized components.

Consider a two-port circularly polarized antenna, one port of which couples to the right circularly polarized mode, and a second port which couples to the left circularly polarized mode of radiation. At microwave frequencies, such an antenna is readily realized by incorporating a quarter-wave plate in a circular waveguide dual-mode transducer as represented in Fig. 1. A signal fed into port A is converted to right circular polarization (RCP) by the device, while a signal fed into port B is converted to left circular polarization (LCP). By controlling the relative phase and amplitudes of inputs to ports A and B, it is possible to generate any desired polarization.

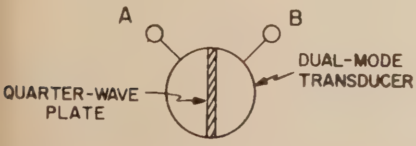

Fig. 1—A two-port circularly polarized antenna.

If signals entering ports A and B (Fig. 1) are the same frequency and equal in amplitude, the two oppositely-sensed CP waves which are generated add vectorally to form a *linearly polarized* wave. The plane of polarization of this linearly polarized wave is determined by the angular phase relationship between the signals entering ports A and B. If signals into ports A and B are made unequal in amplitude, the wave generated by the device will be *elliptically polarized*, and its sense will be determined by the sense of the larger CP component. Thus, the sense and the axial ratio of the resultant wave is controlled simply by varying the ratio of input amplitudes to ports A and B, while the plane of polarization (or orientation of the major axis of the ellipse) is determined by the phase relationship of the two inputs. This simple mechanism, involving just two independent variables, provides complete control of polarization.

As the spatial orientation of the polarized wave is a function of the phase relationship between the right- and left-handed CP components, one can rotate the polarization simply by introducing a relative phase change between the inputs to A and B. By introducing a continuous phase change, as by rotating a continuous type phase shifter, the rotation of polarization can be made continuous. To cause the polarization to rotate at a constant angular rate requires introduction of a constant *rate-of-change-of-phase* between inputs to ports A and B. This, however, amounts to introducing a frequency difference between inputs A and B; hence, to generate a polarized wave which rotates at a constant angular rate, one need only introduce signals at ports A and B which differ in frequency. The relative amplitudes are adjusted to obtain the desired sense and axial ratio, and the frequency difference is chosen to obtain the desired rate of rotation. The rotation frequency will be one-half the frequency difference between inputs to A and B; that is,

$$f_R = \frac{f_A - f_B}{2}.$$

The achievable rate of rotation is limited only by the bandwidth of the RF components.

If one detects this wave by using a linearly polarized antenna, the shape of the modulation envelope would suggest that the transmission was a double-sideband suppressed carrier signal having an effective carrier frequency,

$$f_C = \frac{f_A + f_B}{2}.$$

The RF envelope is the same as would be obtained if a transmitting antenna of the same axial ratio, radiating at frequency f_C, was rotated mechanically about its radiation axis at frequency f_R. For a rotating linear polarization the "sidebands" would be equal in amplitude; for a rotating elliptical polarization, they would be unequal.

In generating a wave having a rotating polarization, a stable rotation rate can be achieved if signals f_A and f_B are derived by using single-sideband generator techniques to develop separate upper and lower sidebands with carrier suppressed.

If one employs a two-mode circularly polarized antenna to receive a wave having a rotating polarization, it follows that the outputs from the RCP and the LCP ports will be at different frequencies, f_A and f_B, in accordance with the equations already given. If the rotating wave is elliptically polarized, this fact will be indicated by amplitude inequality of the two CP outputs.

A "Z-Transform-Describing-Function" for On-Off Type Sampled-Data Systems*

The study of on-off type control systems with sampled data by means of the describing function technique has been made previously by Chow[1] and Russell.[2] In these early investigations, the nonlinear element for which the describing function is derived includes the sampling switch, the zero-order hold circuit, and the on-off relay. For a sinusoidal input whose period is an integral multiple of the sampling period T, the output of the nonlinear element is a periodic rectangular wave. Thus the conventional describing function technique for continuous systems can be applied directly; the nonlinear sampled data system is essentially treated as a continuous system. The method is subject to limitations that a zero-order hold circuit must be used, and there is only one sampling switch in the system which samples the error signal $e(t)$ (Fig. 1).

The present investigation involves the derivation of a new describing function utilizing the Z transformation. The nonlinear element N in this case includes only the on-off relay. The new describing function permits the study of on-off type sampled-data systems of the following types: 1) systems with or without zero-order hold circuit, 2) finite-pulse-width consideration with flat-topped approximation, and 3) systems with more than one synchronized sampling switch.

The block diagram of the nonlinear system with sampled-data under consideration is shown in Fig. 1. The sampling rate of the sampler is assumed to be uniform and the sampling duration is assumed negligible, *i.e.*, ideal sampler. The operational characteristic of the relay is shown in Fig. 2.

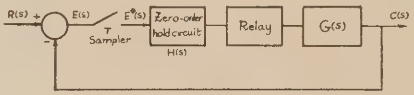

Fig. 1.

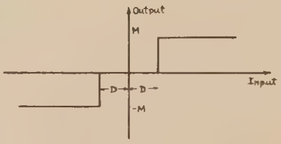

Fig. 2.

If the error signal $e(t)$ is sinusoidal with a period of $T_c = nT$, where T is the sampling period of the sampler, and $n = 2, 3, 4, \cdots$, the output of the sampler $e^*(t)$ is an impulse train of the same period since $e^*(t)$ can have values only at the sampling instants.

As a first step in the study of the system, it is seen that the system behavior is not

* Received by the IRE, November 16, 1959.

[1] C. K. Chow, "Contactor servomechanisms employing sampled data," *Trans. AIEE*, vol. 73, pt. II, pp. 51–64; March, 1954.

[2] F. A. Russell, "Design Criterion for Stability of Sampled-Data On-off Servomechanisms," Ph.D. dissertation, Columbia University, New York, N. Y.; 1953.

altered if the hold circuit and the relay shown in Fig. 1 are exchanged in position; the modified system is shown in Fig. 3.

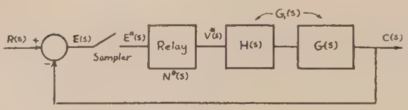

Fig. 3.

It is apparent that the system behavior is not altered by this change. The nonlinear element N in this case contains only the on-off relay. Since the transfer function of the zero-order hold $H(s)$ and $G(s)$ are both linear, the function,

$$G_1(s) = H(s)G(s) = \frac{1-\epsilon^{-Ts}}{s}G(s), \quad (1)$$

is also linear.

The derivation of the describing function $N(z)$ for the relay is based on the assumption that the input signal to the sampler is a sinusoid, and, consequently, the input to N is an impulse train with a sinusoidal envelope. The Z-transform-describing function is defined as the ratio of the Z transform of the output and the Z transform of the input to the relay.

Thus,

the Z-transform describing

$$\text{function } N(z) = \frac{V(z)}{E(z)} \quad (2)$$

where

$$E(z) = Z\text{-transform of } [e(t) = E\cos(at+\phi)]. \quad (3)$$

The output transform of the system shown in Fig. 3 is

$$C(s) = G_1(s)V^*(s) = G_1(s)N^*(s)E^*(s). \quad (4)$$

Thus,

$$\begin{aligned} E(s) &= R(s) - C(s) \\ &= R(s) - G_1(s)N^*(s)E^*(s). \quad (5) \end{aligned}$$

But since

$$E^*(s) = \frac{1}{T}\sum_{n=-\infty}^{\infty} E(s+jnw_s), \quad (6)$$

substituting (5) into (6), we have

$$E^*(s) = \frac{1}{T}\sum_{n=-\infty}^{\infty} [R(s+jnw_s) - G_1(s+jnw_s) \cdot N^*(s+jnw_s)\cdot E^*(s+jnw_s)]. \quad (7)$$

Since for a fixed frequency a, the describing function $N^*(s)$ can be shown to be a linear function of e^{sT},

$$N^*(s) = N^*(s+jnw_s) \quad (8)$$

and it is well known that

$$E^*(s) = E^*(s+jnw_s). \quad (9)$$

Eq. (7) becomes

$$E^*(s) = R^*(s) - G_1^*(s)N^*(s)E^*(s) \quad (10)$$

where

$$R^*(s) = \frac{1}{T}\sum_{n=-\infty}^{\infty} R(s+jnw_s) \quad (11)$$

and

$$G_1^*(s) = \frac{1}{T}\sum_{n=-\infty}^{\infty} G_1(s+jnw_s). \quad (12)$$

Solving for $E^*(s)$ in (10), we get

$$E^*(s) = \frac{R^*(s)}{1+N^*(s)G_1^*(s)} \quad (13)$$

from which

$$\frac{C^*(s)}{R^*(s)} = \frac{N^*(s)G_1^*(s)}{1+N^*(s)G_1^*(s)} \quad (14)$$

or

$$\frac{C(z)}{R(z)} = \frac{N(z)G_1(z)}{1+N(z)G_1(z)}. \quad (15)$$

The study of the condition of self-sustained oscillation of the nonlinear sampled-data system now involves the investigation of

$$G_1(z) = -\frac{1}{N(z)}. \quad (16)$$

In general, if the hold circuit is absent and the finite pulse width has to be considered, the transfer function $H(s)$ can be replaced by

$$H_p(s) = \frac{1-\epsilon^{-ps}}{s} \quad (17)$$

where $p(p \leq T)$ is the pulsewidth (flat-topped approximation).

For a system with feedback element $B(s)$, and a synchronized sampling switch in the feedback path (Fig. 4), the closed-loop transfer function is

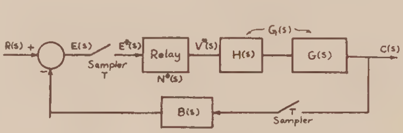

Fig. 4.

$$\frac{C(z)}{R(z)} = \frac{N(z)G_1(z)}{1+B(z)G_1(z)N(z)}, \quad (18)$$

which means that the stability of the system is investigated from

$$B(z)G_1(z) = -\frac{1}{N(z)}. \quad (19)$$

The Derivation of $N(z)$

As an example, the describing function $N(z)$ will be derived for the case when $e(t)$ is a sinusoid of period $T_c=4T$. This means that the relay may have either one or two positive (or negative) corrections during one period T_c. If the number of corrections is designated by Δ (Δ can be either one or two in this case), considering $\Delta=1$, the relay output can be written as

$$\begin{aligned} V(z) &= 1 - z^{-2} + z^{-4} - z^{-6} + \cdots \\ &= \frac{z^2}{z^2+1}. \quad (20) \end{aligned}$$

The Z transform of $e(t) = E\cos(at+\phi)$ is

$$E(z) = \frac{Ez}{z^2 - 2z\cos aT + 1} \cdot [(z-\cos aT)\cos\phi - \sin aT\sin\phi] \quad (21)$$

and for $T_c = T4$,

$$aT = \pi/2, \qquad z = \epsilon^{jwT} = j.$$

Thus,

$$\begin{aligned} N(z) = \frac{V(z)}{E(z)} &= \frac{z^2}{z^2+1} \times \frac{z^2+1}{Ez(z\cos\phi - \sin\phi)} \\ &= -\frac{1}{E} \times \frac{1}{\cos\phi + j\sin\phi}. \quad (22) \end{aligned}$$

A Note on the Steady-State Response of Linear Time-Invariant Systems to General Periodic Input*

In the following discussion, a simple procedure is presented for obtaining the steady-state response of linear systems to nonsinusoidal periodic inputs. This procedure is based on applying the final value theorem to the modified z-transform of the output. It is known that the modified z-transform method is widely used for the analysis of sampled-data and finite pulsed systems; its use to the above problem is readily evident. A very brief discussion of this method is hereby presented.

Suppose that the Laplace transform of part of the output[1] $C_1(s)$ (which contains only finite poles and has a higher degree denominator in s than numerator) is given. Then its modified z-transform denoted as $C_1^*(z, m)$ is given by the following complex convolution integral.[2]

$$\begin{aligned} C_1^*(z, m)_{z=e}\big|_{Ts} &= Z_m[C_1(s)] \\ &= \frac{e^{-Ts}}{2\pi j}\int_{c-j\infty}^{c+j\infty} C_1(p)\frac{e^{mpT}}{1-e^{-T(s-p)}}\,dp, \\ & \qquad 0 \leq m \leq 1 \quad (1) \end{aligned}$$

where T is the input period.

One method of evaluating the above integral is to integrate around a closed path in the left half of the complex p-plane that encloses all the finite singularities of $C_1(p)$, applying the residue theorem. In this case (1) becomes

$$C_1^*(z, m) = z^{-1}\sum_{\text{poles of } C_1(p)} \text{residue of}\left[C_1(p)\frac{e^{mpT}}{1-e^{pT}z^{-1}}\right]\Bigg|_{z=e^{Ts}}. \quad (2)$$

For instance, if $C_1(s) = 1/s+a$, (2) yields for its modified transform

---

* Received by the IRE, December 11, 1959; revised, January 14, 1960.

[1] The Laplace transform of the output in this case can always be represented as

$$C(s) = C_1(s)\frac{1}{1-\epsilon^{-Ts}}.$$

[2] E. I. Jury, "Sampled Data Control Systems," John Wiley and Sons, Inc., New York, N. Y., chs. 2, 9; 1958.

$$C_1^*(z, m) = Z_m\left[\frac{1}{s+a}\right] = \frac{e^{-amT}}{z - e^{aT}}, \quad 0 < m < 1. \quad (3)$$

In the literature, extensive tables of modified z-transform pairs[2,3] are given that can be readily used for more complicated forms of $C_1(s)$. However, in some cases $C_1(s)$ (having simple poles) can be represented by partial fraction expansion as the sum of single time constants. Then its modified z-transform can be readily obtained as the sum of the terms of the form of (3).

The final value theorem developed for the modified z-transform can be briefly stated as follows:[2,3]

$$\lim_{n\to\infty} c(n, m)T = \lim_{z\to 1} \frac{z-1}{z} C^*(z, m), \quad 0 \le m \le 1, \quad (4)$$

if the limit exists where $C^*(z, m)$ is the modified z-transform of the output $C(s)$.

Furthermore, the continuous output in a closed form is also given by the inverse z-transform[2] as follows:

$$c(n, m)T = Z^{-1}[C^*(z, m)] = \frac{1}{2\pi j}\int_\Gamma C^*(z, m)z^{n-1}dz, \quad 0 \le m \le 1$$

$$t = (n - 1 + m)T$$

$$n = \text{positive integer} \quad (5)$$

where Γ is a closed path of integration in the z-plane that enclosed all the poles of $C^*(z, m)$.

For the purpose of this discussion only the final value theorem is applied to obtain the steady-state response. The following two cases are discussed:

Case 1:

$$C(s) = F(s) + C_1(s)\frac{1}{1 - e^{-Ts}}. \quad (6)$$

$F(s)$ in (6) is a rational function of s and has a final value f_{ss} that can be obtained from $\lim_{s\to 0} sF(s)$. Hence, the steady-state output yields

$$c_{ss} = f_{ss} + \lim_{z\to 1}\frac{z-1}{z} Z_m\left[C_1(s)\frac{1}{1-e^{-Ts}}\right] = f_{ss} + \lim_{z\to 1} Z_m[C_1(s)],$$

since

$$Z_m\left[\frac{1}{1 - e^{-Ts}}\right] = \frac{z}{z-1}\bigg|_{z=e^{Ts}}. \quad (7)$$

Case 2:

$$C(s) = F_1(s)\frac{F_2(e^{\tau_n s})}{1 - e^{-Ts}} = C_1(s)\frac{1}{1-e^{-Ts}}; \quad (8)$$

the sum of all τ_n is less than T.

In general the steady-state output of (8) is composed of several regions depending on (τ_n); thus in obtaining the modified z-transform of (8) the several regions should be observed. Mathematically, this indicates that due care should be exercised in observing the convergence of the integral along the infinite semicircle in evaluating (1). This is best illustrated with the given example.

Example a: Consider the steady-state voltage of $v_0(t)$ across the condenser[4] in Fig. 1(a) for an input of the form of rectified sine wave shown in Fig. 1(b).

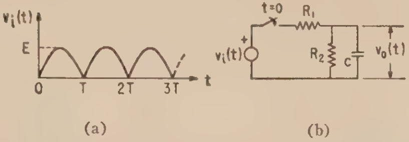

Fig. 1—(a) Rectified sine wave. (b) A parallel RC circuit with series resistance.

$V_0(s)$ in this example equals

$$V_0(s) + \frac{K}{s^2 + (\pi/T)^2}\,\frac{1 + e^{-Ts}}{1 - e^{-Ts}} \times \frac{1}{s+a} \quad (9)$$

where

$$K = \frac{\pi E}{TR_1c}, \qquad a = \frac{R_1 + R_2}{R_1R_2c}.$$

The steady-state voltage is given by

$$V_{0ss} = \lim_{z\to 1} 2KZ_m\frac{1}{[s^2 + (\pi/T)^2][s+a]},$$

since

$$\lim_{z\to 1} Z_m[1 + e^{-Ts}]\,\big|_{z=e^{Ts}} = 2. \quad (10)$$

By using partial fraction expansion of

$$\frac{1}{[s^2 + (\pi/T)^2][s+a]}$$

the modified z-transform can be obtained.[5] The steady-state voltage is obtained by applying the final value theorem.

$$V_{0ss} = \left[\frac{K}{a^2 + (\pi/T)^2}\right]\left[\frac{2e^{-amT}}{1 - e^{-aT}} - \cos \pi m + \frac{aT}{\pi}\sin \pi m\right], \quad 0 \le m \le 1. \quad (11)$$

Example b: This example illustrates the application of the theorem to a periodically varying (cyclic) pulsed system.[6] Obtain the steady-state voltage of $v_R(t)$ across the resistance shown in Fig. 2(a) for a periodically varying (cyclic) input shown in Fig. 2(b).

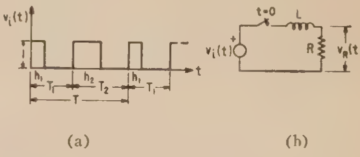

Fig. 2—(a) Periodically time-varying (cyclic) wave. (b) Series RL circuit.

The Laplace transform of the voltage across the resistance, R,

$$V_R(s) = R/L\frac{[1 - e^{-h_1s} + e^{-T_1s}(1 - e^{-h_2s})]}{s(s + R/L)(1 + e^{-Ts})}$$

$$= \frac{[1 - e^{-h_1s} + e^{-T_1s} - e^{-(T_1+h_2)s}]}{s(1 - e^{-Ts})}$$

$$- \frac{[1 - e^{-h_1s} + e^{-T_1s} - e^{-(T_1+h_2)s}]}{(s + R/L)(1 - e^{-Ts})} \quad (12)$$

In this case the steady-state is composed of four regions as follows: I, $0 \le mT \le h_1$; II, $h_1 \le mT \le T_1$; III, $T_1 \le mT \le h_2 + T_1$; IV, $T_1 + h_2 \le mT \le T$. For region I, the modified z-transform yields[7]

$$V_R^*(z, m) = \frac{1 - z^{-1} + z^{-1} - z^{-1}}{(z-1)(1-z^{-1})} - \frac{[1 - e^{-(T-h_1)R/L}z^{-1} + e^{-(T-T_1)R/L}z^{-1} - e^{-(T-T_1-h_2)R/L}z^{-1}]}{(z - e^{-(R/L)T})(1 - z^{-1})}e^{-mTR/L}. \quad (13)$$

The steady-state value

$$v_{ss} = \left[1 - \frac{(1 - e^{-(T-h_1)R/L} + e^{-(T-T_1)R/L} - e^{-(T-T_1-h_2)R/L})}{(1 - e^{-(R/L)T})}e^{-mTR/L}\right], \quad 0 \le mT \le h_1 \quad (14)$$

It is of interest to note that for a fixed pulse-width, $h_2 = 0$, $h_1 = h$, $T_1 = T$, the steady-state voltage

$$V_{ss} = \left[1 - \frac{(1 - e^{-(T-h)R/L})}{1 - e^{-(R/L)T}}e^{-mTR/L}\right], \quad 0 \le mT \le h. \quad (15)$$

For the continuous case, $h_1 = T_1 = T$, $h_2 = T = T_1$, we obtain unity as the steady-state value.

Similarly for regions II, III, and IV the following is obtained for this general case:

---

[3] J. Cypkin, "Theory of Pulse Systems," State Press for Physics and Mathematical Literature, Moscow, USSR, ch. 4; 1959.

[4] D. K. Cheng, "Analysis of Linear Systems," Addison Wesley Publishing Co., Inc., Reading, Mass., ch. 7; 1959.

[5] It should be noted that $V_0^*(z, m)$ can also be obtained by the use of available extensive tables to be found in refs. 2 and 3.

[6] E. I. Jury and T. Nishimura, "Analysis of finite pulse systems with periodically varying sampling rate and pulse width," to be published in *Trans. AIEE;* October, 1959.

[7] It should be noted that for region I,

$$Z_m\left[\frac{e^{-h_1s}}{s + (R/L)}\right] = Z_m\left[\frac{e^{-Ts}\,e^{(T-h_1)s}}{s + (R/L)}\right] = \left[z^{-1}\frac{e^{-(T-h_1)(R/L)}}{z - e^{-(R/L)T}}e^{-mTR/L}\right].$$

This stems from the consideration of the convergence of the integral in (1) in the left half of the p-plane (see ref. 2).

$$v_{ss} = 0 - \left(\frac{1 - e^{h_1 R/L} + e^{-(T-T_1)R/L} - e^{-(T-T_1-h_2)R/L}}{1 - e^{-(R/L)T}}\right) e^{-mTR/L}, \quad h_1 \leq mT \leq T_1; \qquad \text{II.} \quad (16)$$

$$v_{ss} = 1 - \frac{\left[1 - e^{h_1 R/L} + e^{T_1 R/L} - e^{-(T-T_1 h_2)R/L}\right]}{1 - e^{-(R/L)T}} e^{-mTR/L}, \qquad T_1 \leq mT \leq T_1 + h_2; \text{ III.} \quad (17)$$

$$v_{ss} = 0 - \left(\frac{1 - e^{h_1 R/L} + e^{T_1 R/L} - e^{(T_1+h_2)R/L}}{1 - e^{-(R/L)T}}\right) e^{-mTR/L}, \qquad T_1 + h_2 \leq mT \leq T; \quad \text{IV.} \quad (18)$$

A plot of v_{ss} for the four regions is shown in Fig. 3.

In conclusion, an alternate[8-10] and in some cases a simpler procedure is introduced in this work than is sometimes used for determining the steady-state response.[4] The procedure is based on assuming that the periodic input is described in time which is Laplace transformable and that the system is stable. It might be also mentioned that the procedure introduced has also been applied to obtain a closed form of an infinite convergent Fourier series.[2]

WWV and WWVH Standard Frequency and Time Transmissions*

The frequencies of the National Bureau of Standards radio stations WWV and WWVH are kept in agreement with respect to each other and have been maintained as constant as possible with respect to an improved United States Frequency Standard (USFS) since December 1, 1957.

The nominal broadcast frequencies should, for the purpose of highly accurate scientific measurements, or of establishing high uniformity among frequencies, or for removing unavoidable variations in the broadcast frequencies, be corrected to the value of the USFS, as indicated in the table below.

The characteristics of the USFS, and its relation to time scales such as ET and UT2, have been described in a previous issue,[1] to which the reader is referred for a complete discussion.

The WWV and WWVH time signals are also kept in agreement with each other. Also they are locked to the nominal frequency of the transmissions and consequently may depart continuously from UT2. Corrections are determined and published by the U. S. Naval Observatory. The broadcast signals are maintained in close agreement with UT2 by properly offsetting the broadcast frequency from the USFS at the beginning of each year when necessary. This new system was commenced on January 1, 1960. The last time adjustment was a retardation adjustment of 0.02 *s* on December 16, 1959.

Electronically-Variable Phase Shifters Utilizing Variable Capacitance Diodes*

In many applications which require electronically-variable phase shifters for operation in the UHF and microwave region, ferrite devices or traveling-wave tubes are not suitable because of excessive weight, size, or demand for control power. The use of variable capacitance diodes for high-frequency phase shifting has been under study for more than a year and has resulted in a compact, fast, and efficient electronically-controlled phase shifter. On the debit side, the device is at present useful only at lower power levels and also has limited phase shift-bandwidth product.

If a transmission line is terminated in a pure reactance, all the energy incident upon the termination is reflected and the phase shift of the reflected wave is a function of the magnitude of the reactance. When the reactive termination is used in a circuit which completely separates the incident and reflected waves (circulator or a properly phased balanced circuit), a variation in the terminating reactance will produce a change in the phase of the reflected output wave and the complete unit will be well matched and efficient.

In practice, two variable capacitance diode terminations have been used with hybrid rings, hybrid junctions, and certain types of 3-db couplers. One of the simplest configurations results if the coupling circuit is a waveguide short-slot coupler or its coaxial or stripline equivalent, as shown in Fig. 1. The phase of the output wave varies as the bias voltage on the diodes is changed. Stripline techniques permit miniaturization, and very little control power is required because of the high reverse impedance of the diodes. Some RF loss is introduced by the spreading resistance of the diodes, but this is not serious if the diode has reasonably high Q.

In this circuit, the rate of change of phase shift with reactance is greatest at $X=0$. Therefore, for maximum phase shift, the diode termination should be adjusted for resonance in the center of the diode's capacity variation range. This can be done by properly adjusting "stubs" behind the diode. Maximum insertion loss also occurs at resonance, so phase shift can be traded, to some extent, for decreased insertion loss.

Phase shifters utilizing variable capacitance diodes have been constructed at 0.5, 1.0, 6.0, and 9.0 kmc. A phase shift of over 180° was obtained with a single unit at 1 kmc, 110° at 6 kmc, and 41° at 9 kmc. Maximum insertion lose varied from 1.2 db at 1 kmc to 3.9 db at 9 kmc, although the latter figure was improved considerably by decreasing phase shift. Fig. 2 shows the phase-shift and insertion-loss variation with bias voltage at 1 kmc.

The data was obtained at a power level of 1 milliwatt using Hughes Products (HPA 2800) diodes. These diodes have a capacity variation from about 2.5 to 1.0 $\mu\mu f$ with a bias voltage change from 0 to 5 volts; the reverse breakdown voltage is about 7

---

* Received by the IRE, August 24, 1959.

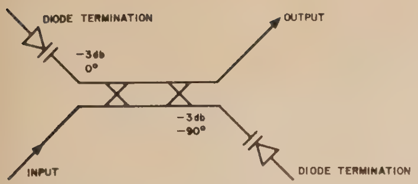

Fig. 1—A variable capacitance diode phase shifter using a 3-db coupler.

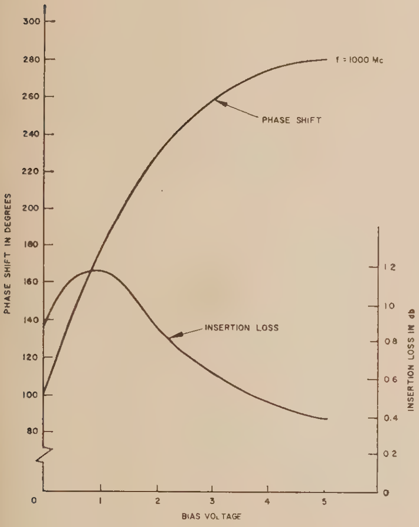

Fig. 2—Phase shift and insertion loss as a function of diode bias at 1 kmc.

volts. The insertion loss of phase shifters using these diodes increases with RF power; at 20 mw, for example, the loss is 6.4 db. This rapid increase in loss at higher powers results in a limiting action and is caused by power lost in harmonic generation and because of the onset of both forward and backward diode conduction.

In order to increase the operating power level of the phase shifter, a high-Q variable capacitance diode with a high reverse breakdown voltage is needed. This feature would permit higher RF voltages without driving the diode into conduction, and harmonic generation would be reduced because the capacity variation with voltage would be decreased. Unfortunately, high reverse breakdown voltage and small spreading resistance are somewhat incompatible. However, some improvement over parametric amplifier diodes is possible and further development may improve the power handling capability of the phase shifter. The phase-shift bandwidth product can be increased by the use of several diodes in a traveling-wave circuit.

The diode phase shifter is a compact and very fast device requiring negligible control power. It may be useful in electronically-scanned receiving arrays, in low power satellite transmitting arrays and in many other applications.

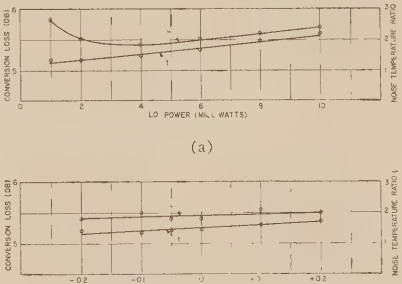
Gallium Arsenide Microwave Diode at *X* Band*

J. J. Wysocki of RCA has kindly supplied us with five of the GaAs microwave diodes described by Jenny[1] in order that we might make measurements at X band.

The measurements were made at 9375 mc and the diodes were matched to the local oscillator. As originally received, the diodes performed rather poorly; typical values of conversion loss L and noise temperature ratio t were 7 db and 3 times, respectively.

The diodes were then rebuilt by resetting the whisker on the crystal so as to maximize the short-circuit rectified current produced by the local oscillator. Fig. 1 gives the results for a *typical* rebuilt crystal. Note the lack of bias dependence [Fig. 1(b)]. The best diode (of approximately 15 resets) had an L of 5.6 db and a t of 1.14 times.[2]



(a)

(b)

Fig. 1—Performance of typical GaAs microwave diode at X band. (a) The dc voltage bias is constant at zero volts. (b) The *LO* power is constant at four milliwatts.

Thus it appears that GaAs diodes can be made with L and t at X band which compare favorably with silicon and germanium diodes. In addition, they are less bias sensitive than germanium diodes and, judging from band-gap data, are promising for high temperature applications.

A Wide Band Phase Shifter*

One of the several applications which require a network giving a 90° phase shift over a wide band of frequencies is the phase-cancelling method of single sideband generation.[1] There are various networks which give an almost constant phase shift of 90° over the audio band.[2]

The arrangement here described achieves the same end in a novel way. It provides exactly 90° phase shift over a bandwidth determined by the characteristics of the filters used in it.

The signal is mixed in a balanced mixer [① in Fig. 1] with a local oscillation (f_0) of higher frequency than the highest modulation frequency used. Of the various combinations and harmonics that result, the upper sideband is selected by a filter. This sideband is then demodulated in each of two balanced mixers [② and ③ in Fig. 1] by mixing again with (f_0) in one case, and by mixing with (f_0) shifted through 90° in the other. Of the resulting combinations and harmonics, the lower sideband is selected in each case, giving the original signal at two outputs differing in phase by 90°. The action should be clear from the diagram.

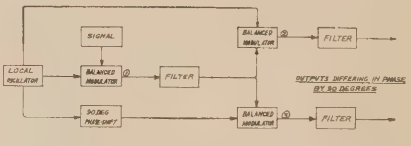

Fig. 1—90° phase shifter.

After mixing in mixer ①, the lower sideband could have been used but in this case, the signal voltage appearing in the modulator output because of lack of balance will not be attenuated in the subsequent filter since this would have to pass frequencies of the same order. This could then be obviated only by raising the local oscillator frequency to a value of at least twice the highest modulation frequency used. This would be undesirable since it would render the separation of desired frequencies close to the local oscillator frequency more difficult.

Band-pass filters would be better than high-pass or low-pass filters because of the presence of harmonics and various other undesired combination frequencies resulting from the modulators. Since the powers involved are quite low, the same techniques can be used as in carrier telephony, whereby simple rectifier modulators may be used, simplifying the apparatus. Clearly, any other desired constant phase shift may be obtained by varying the phase of (f_0) supplied to modulator ③.

Experiments carried out indicate that the method gives the results expected.

Very sincere thanks are due Dr. F. Tank for his constant encouragement and for all the facilities which he has made available.

Bandwidth of Lower Sideband Parametric Up-Converters and Parametric Amplifiers*

In an article by Rowe,[1] an expression is derived for the gain of a lower-sideband up-converter as a function of a stability factor α and a frequency factor x. Because of the complexity of this expression, the bandwidth of the device as a function of α could not be expressed in closed form. A simplified form of the expression allows the bandwidth to be expressed directly as a function of α, thereby permitting evaluation of the bandwidth and the $(\text{gain})^{1/2}$-bandwidth product for any value of gain from zero to infinity.

In Rowe[1] an expression for the conversion gain from IF to the lower side frequency was given as follows:[2]

$$G_{tl-} = \frac{f_{-m}}{f_{lm}} \frac{4\alpha}{(1-\alpha)^2} \frac{1+x^2}{1+\dfrac{(3+\alpha^2)}{(1-\alpha)^2}x^2+\dfrac{(3+2\alpha)}{(1-\alpha)^2}x^4+\dfrac{1}{(1-\alpha)^2}x^6}, \qquad (1)$$

where

α = a stability factor,
x = the relative frequency deviation,
f_{lm} = the IF, at midband, and
f_{-m} = the lower side frequency at midband.

The down-conversion gain is identical to the above expression except that the ratio f_{lm}/f_{-m} replaces the ratio of f_{-m}/f_{lm}.

The bandwidth of the system is proportional to x_0, where x_0 is the value of x which causes the gain to drop 3 db below its midband ($x=0$) value. It was stated by Rowe[1] that the value of x_0 as a function of α could not be found in closed form; therefore, two special cases were selected for calculating the bandwidth.

In a separate derivation, the writer of this letter, by a different approach from that used by Rowe, arrived at

$$G_{tl-} = \frac{f_{-m}}{f_{lm}} \frac{4\alpha}{(1-\alpha)^2} \cdot \frac{1}{1+\dfrac{(2+2\alpha)}{(1-\alpha)^2}x^2+\dfrac{1}{(1-\alpha)^2}x^4}. \qquad (2)$$

In seeking compatibility between this expression and that obtained by Rowe, it was found that the numerator of Rowe's expression is a factor of the denominator, and that (1) and (2) are identical.

To find x_0,

$$\frac{1}{(1-\alpha)^2}x^4 + \frac{2+2\alpha}{(1-\alpha)^2}x^2 = 1,$$

must be solved for x. The two real roots are

$$x_0 = \pm\left[\sqrt{2(1+\alpha^2)} - (1+\alpha)\right]^{\frac{1}{2}}. \qquad (3)$$

For α very near unity this reduces to

$$x_0 \approx \pm \tfrac{1}{2}(1-\alpha)$$

which agrees with Rowe's result.

From (3) the bandwidth and $(\text{gain})^{1/2}$-bandwidth product of the up-converter may be found directly as a function of all values of α for $0 \leq \alpha < 1$, where $\alpha = 1$ represents the threshold of oscillation.

If the negative admittance at the IF or lower side frequency port is used to give gain by reflection, it develops that when the gain is large compared to unity, the same frequency characteristics apply.

Noise Measurements on an *M*-Type Backward-Wave Amplifier*

Up to the present time, full utilization of crossed-field amplifiers has not been realized because of the high level of noise output associated with these devices. The noisiness of the crossed-field beam is usually accompanied by large electron currents collected on an electrode, known as the sole, even when it is biased negatively with respect to the cathode. This aspect of the noise behavior has been extensively studied but is not yet fully understood.[1] The purpose of this letter is to report noise measurements that have been made on an experimental *M*-type backward-wave amplifier. A schematic diagram of the electrode configuration of the device is presented in Fig. 1. The unique feature of this tube is the electron gun design which is based on an analysis by Kino and Kirstein.[2,3] The gun is designed to produce a well-defined, space-charge limited, laminar-flow electron beam with negligible rippling and spread as the beam drifts to the collector. Such beam behavior has been visually observed and is accompanied by negligible sole current. The area convergence of the electron gun is four to one resulting in a beam whose thickness is one-seventh of the line-sole spacing. The width of the beam is approximately one-half that of the sole. An oxide cathode is used in the gun.

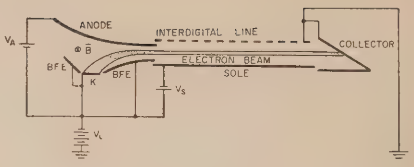

Fig. 1—Schematic of experimental crossed-field backward-wave amplifier.

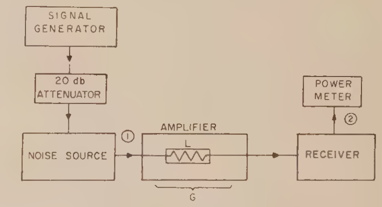

Fig. 2—Experimental arrangement for noise figure measurements.

Three types of noise measurements have been performed: 1) noise figure, 2) signal-to-noise ratio, 3) velocity spread. A block diagram of the basic arrangement for measuring the noise figure is shown in Fig. 2. Under the conditions that the bandwidth of the receiver is much less than the bandwidth of any of the other components and that the impedance of the noise source as seen by the backward-wave amplifier is matched, the noise figure of the amplifier is expressed as,

$$\text{N.F.} = \frac{1}{G}\left[\frac{\left(\dfrac{P_{2\text{on}}}{P_r}-1\right)}{\left(\dfrac{P_{2\text{off}}}{P_r}-1\right)}\left(\frac{P_{ns}}{LP_1}\right)+1\right]$$

where

P_{ns} = noise source output power in excess of thermal noise.
$P_1 = kTB$, the thermal noise input to the tube under matched conditions.
$P_{2\text{off}}$ = power delivered to the power meter with the electron beam off and the noise source on.
$P_{2\text{on}}$ = power delivered to the power meter with the electron beam on and the noise source off.
P_r = noise power at the receiver with both electron beam and noise source off.
G = amplifier gain.
L = input power/output power is the cold loss through the amplifier.

The results of the measurements are presented in Table I. Accuracy of the noise figure is ±2 db, and the 3-db bandwidth of the amplifier is 0.9 per cent of the signal frequency. The dc beam transmission to the collector during these measurements was between 88 and 92 per cent. The receiver bandwidth was 300 kc.

Signal-to-noise ratio measurements were performed for a variety of operating conditions but all with a well-focused electron beam at space-charge limited emission. No distinct coherent sidebands were observed at any appreciable level above the noise output of the tube within a 40-mc band cen-

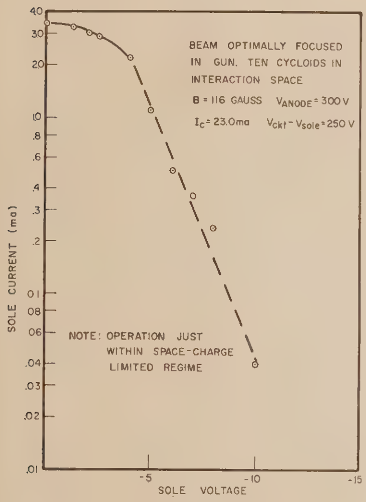

Fig. 3—Sole current distribution.

tered about the signal frequency. The results of these measurements are summarized in Table II. The measured signal-to-noise ratios are in the same range as has been reported for a forward-wave M-type amplifier.[4] The significance of the results presented in Table II is that this type of amplifier can maintain good sensitivity over an extremely wide range of input signal level.

Finally, a few measurements of the velocity spread in the electron beam have been achieved. For space-charge limited conditions and a well-focused beam in the gun region, the line-sole electric field was decreased so that the beam path in the drift region came close to the sole. The beam thickness remained approximately constant throughout the drift region. The velocity spread in the beam can then be estimated from the sole current-sole voltage distribution. This distribution was found to be not half-Maxwellian, as can be seen in Fig. 3. However, the distribution is approximately half-Maxwellian at low sole currents and on this basis, the equivalent temperature of the electron beam is 40,900°K. This corresponds to a decrease of sole current by a factor e at a sole potential of -1.5 volts. From these measurements, it is concluded that even with an electron gun which produces a well-focused laminar beam the characteristic energy spread of crossed-field tubes is still present, although perhaps to a lesser extent than in similar tubes employing less well-behaved beams.

However, the noise figure and signal-to-noise ratio of this M-type backward-wave amplifier has been measured and is found to be of the same magnitude as in O-type tubes when attention was first directed toward their noise problem. No attempt was made to design the present tube for low noise output. Therefore, it is entirely possible that the noise figure of an M-type backward-wave amplifier, utilizing a well-behaved beam, can be reduced further.

On the Start Oscillation of the O-Type Backward Wave Oscillator*

The conditions that the O-type backward wave oscillator satisfy at the start of oscillation are such that θ and CN satisfy the following:

$$\eta^3-2\theta\eta^2+(\theta^2-H^2)\eta+(2\pi CN)^3=0, \quad (1)$$

where the roots of (1), η_1, η_2, and η_3 must satisfy

$$\frac{\eta_3-\eta_2}{\eta_1}e^{j\eta_1}\cos 2+\frac{\eta_1-\eta_3}{\eta_2}e^{j\eta_2}+\frac{\eta_2-\eta_1}{\eta_3}e^{\eta_3}=0;$$

and

$\theta=(\beta_c-\beta_e)L,$
$H=\omega_pL/u_0,$
$CN=$the CN parameter of Pierce's,
$\beta_c=$propagation constant of the unperturbed circuit wave,
$\beta_e=\omega/u_0,$
$u_0=$electron drift velocity,
$L=$length of interaction space,
$\omega_p=$plasma frequency of the beam,
$\omega=$tube oscillation frequency.

Among the various discussions of the solutions of (1), Heffner[1] gave the numerical values of θ corresponding to the first two oscillation modes (designated $n=0$ and 1 modes) for values of H ranging from 0 to 10. Gould[2] further gave the asymptotic solutions for $H\gg1$ in the terms of a coupled-mode theory. Physically, this corresponds to the asymptotic case in which the space charge density of the electron beam is so high that the propagation constants of the unperturbed slow and fast space-charge waves are far enough apart that the fast space-charge wave can be neglected in so far as the interaction between the slow space-charge wave and the backward circuit wave is concerned. Heffner's and Gould's results are reproduced in Fig. 1.

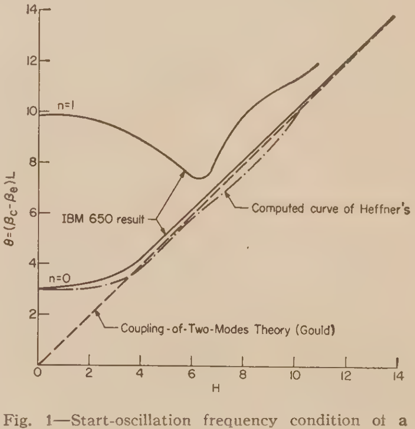

Fig. 1—Start-oscillation frequency condition of a matched backward-wave oscillator.

In connection with a recent study of some anomalous behavior of backward-wave oscillators, we had the occasion to obtain the solution of (1) on the IBM 650 computer.[3] The result thus obtained (see Fig. 1) showed an interesting disagreement with Heffner's result. Although the quantitative discrepancy is small, the physical meaning of this discrepancy seems significant. It is noticed that for the lowest mode ($n=0$), Heffner's curve intersects the asymptotic two-wave solution of Gould at $H\approx3.5$. For $H>3.5$ the value of θ according to Heffner's result becomes less than the asymptotic solution. The

curve corresponding to the IBM 650 result, however, lies above the asymptotic two-wave solution for all values of H and asymptotically approaches the latter from above as H increases. In view of the previous discussion about the physical meaning of the solutions of (1) and the asymptotic two-wave solution of Gould, the implication of the discrepancy is immediately clear. Our result indicates that the effect of the fast space-charge wave on the interaction of the slow space-charge wave and the backward circuit wave is largest when the phase velocities of the three waves are the closest, or H is small. As H increases, or as the phase velocity of the fast space charge wave becomes increasingly faster than the synchronous phase velocity of the circuit wave and the slow space-charge wave, the interaction between the latter two is affected less and less by the fast space-charge wave. Such an effect is, however, always present.

Heffner's result indicates, on the other hand, that the effect of the fast space-charge wave on the interaction of the circuit wave and the slow space-charge wave is opposite for $H<3.5$ and $H>3.5$. (θ increases or decreases for $H<$ or $H>3.5$, respectively, because of the presence of the fast space-charge wave.) At $H\approx 3.5$, the fast space-charge wave has no effect on the interaction of the circuit wave and the slow space-charge wave in so far as θ (or, equivalently, the tube oscillation frequency) is concerned. On purely intuitive grounds, it seems also that our IBM 650 result is the more reasonable of the two.

Negative Resistance in Transistors Based on Transit-Time and Avalanche Effects*

In this communication, we propose a simple semiconductor device which should exhibit a negative resistance characteristic at frequencies of the order of the carrier inverse transit time in the space-charge or depletion region of a reverse-biased p-n collector junction. Previously, others have proposed negative resistance structures using transit-time effects[1] or both transit-time effects and avalanche multiplication.[2] We also use the latter combination in our device. Our device, structurally speaking, is identical to a transistor; however, it requires a rather small collector capacity and extrinsic base resistance.

The basic idea underlying its operation is as follows: Consider a grounded-base transistor biased at the emitter with a direct current source which produces the usual minority carrier distribution in the base region. The collector junction is reverse biased. The collector-base terminals are the two terminals at which the active impedance is to be produced. Suppose, now, that an alternating voltage of high frequency (far exceeding the α-cutoff) is applied to the collector. In response to this, the boundaries of the collector space-charge region will pulsate in position at the same frequency. We are interested in the base-side edge only. Because of the oscillation of the latter, the injected emitter minority current entering the space-charge region and flowing to the collector is modulated at the plane of the space-charge boundary. If the frequency and amplitude are high enough, the minority carriers will fail to follow the moving space-charge edge and the above current will actually be "bunched." For the small signal case, however, only a sinusoidal modulation of the direct current will be produced. We consider the latter case in this communication. For a suitably chosen collector bias voltage, near avalanche breakdown, this alternating component of particle current, when it arrives at the collector junction, will give rise to an additional (multiplied) particle current consisting of the opposite type carrier. This multiplied component will dominate the injected component in magnitude when the avalanche multiplication factor exceeds two. Because of the finite carrier transit time through the space-charge region (from the edge to the junction plane), there will be frequencies at which the multiplied particle current (or a component of it) is 180° out of phase with the collector signal. At these frequencies, a negative resistance will be produced which may be utilized in amplifiers and oscillators.

Outline of Analytic Treatment

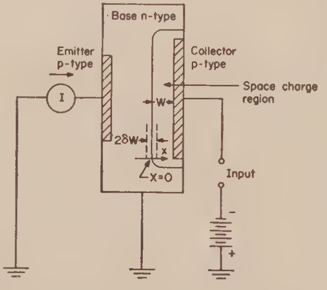

Fig. 1—Schematic presentation of device.

Fig. 1 shows a schematic sketch of a p-n-p alloyed transistor which will serve as our model. Denote the width of the space-charge region in the base- or n-region by W and let the amplitude of its boundary modulation produced by an applied collector signal be called δW. We assume that at the instantaneous edge of this boundary, the injected hole density produced by the emitter bias current is approximately zero. An approximate solution of the diffusion equation in the base region gives

$$p(x) = -\frac{J_{\mathrm{dc}}}{qD}x - \frac{J_{\mathrm{dc}}\delta W}{qD} \cdot \exp\left(\sqrt{\frac{\omega}{2D}}(1-i)x\right)\exp - i\omega t. \quad (1)$$

In (1), $J_{\mathrm{dc}}=I_{\mathrm{dc}}/A$ is the density of the injected minority carrier current I_{dc} entering the space-charge region, where A is the cross-sectional area. In the usual notation, q is the electronic charge, D the diffusion constant of holes, ω the frequency, and t is the time.

From (1), one obtains the alternating particle current density j_i entering the space-charge region at approximately $x=0$

$$j_i = -qD\left.\frac{\partial p}{\partial x}\right|_{x=0} = J_{\mathrm{dc}}\delta W\sqrt{\frac{\omega}{D}}\exp\left(-\frac{i\pi}{4}\right)\exp(-i\omega t). \quad (2)$$

This particle current gives rise to a space-charge wave which travels to the collector junction and produces an additional multiplied component consisting of electrons which travel back in the reverse direction. Assuming that the multiplication takes place at the collector junction plane $x=W$ and that the drift velocity is constant and saturated at a constant value v, then the space-charge wave is given by

$$\rho(x) = \frac{j_i}{v}\left[\exp ikx - \overline{m}\exp - ik(x-2W)\right] \cdot \exp - i\omega t \quad (3)$$

where $k=\omega/v$, $\bar{m}=m-1$, and m is the avalanche multiplication factor.

The calculation proceeds now as follows: Using Poisson's equation, we can obtain from (3) an additional voltage developed across the space charge. For the integration we assume zero electric field at the base-side edge of the space-charge region. We also assume that ρ, as given by (3), is small as compared to the built-in space charge resulting from the ionized donor atoms. We designate this additional voltage by V_{particle}. Similarly, we can calculate an additional current density j_{particle} consisting of the true particle current and a displacement current. Since it is immaterial where this current is calculated, we chose the plane $x\approx 0$. At this plane, the additional displacement current vanishes. The total impedance looking into the base-collector terminals thus may be written

$$Z = \frac{1}{A}\,\frac{V_{\mathrm{displacement}} + V_{\mathrm{particle}}}{j_{\mathrm{displacement}} + j_{\mathrm{particle}}} \approx \frac{V_{\mathrm{displacement}}}{j_{\mathrm{displacement}}A} + \frac{V_{\mathrm{particle}}}{j_{\mathrm{displacement}}A} - \frac{V_{\mathrm{displacement}}\,j_{\mathrm{particle}}}{(j_{\mathrm{displacement}})^2 A}. \quad (4)$$

In (4), $V_{\mathrm{displacement}}$ and $j_{\mathrm{displacement}}$ are the voltage and the current density which would be produced in the absence of any injected current by the oscillating space-charge edge. In the expansion (4), which holds for sufficiently small injected current, the first term is simply the usual space-charge capacitive

---

* Received by the IRE, August 27, 1959; revised, October 2, 1959.

[1] W. Shockley, "Negative resistance arising from transit time in semiconductor diodes," *Bell Sys. Tech. J.*, vol. 33, pp. 799–826; July, 1954.

term of the collector junction $(-i\omega\epsilon A/W)^{-1}$, which is purely reactive. The remaining two terms are contributions of the injected mobile charge. By carrying out the above outlined integration, we obtain from these latter two terms the additional impedance

$$Z_{\text{add}} = \frac{I_{\text{dc}}W^3}{A^2\sqrt{D\tau\epsilon v^2\rho_f}}\left\{\frac{\exp\left(-i\frac{\pi}{4}\right)}{\sqrt{\omega\tau}} \cdot\left[\frac{(\exp i\omega\tau - 1)}{i(\omega\tau)^2}(\exp i\omega\tau)\right]\right\}. \quad (5)$$

The quantity in the curly brackets denoted $f(\omega\tau)$, is plotted in Fig. 2 as a function of $\omega\tau$ for $\bar{m}=1$ and $\bar{m}=2$. It is seen that at approximately $\omega\tau=0.8\pi$ and $\bar{m}=2$ there is a negative resistance region. The magnitude of the negative resistance, according to (5), obviously increases linearly with bias current.

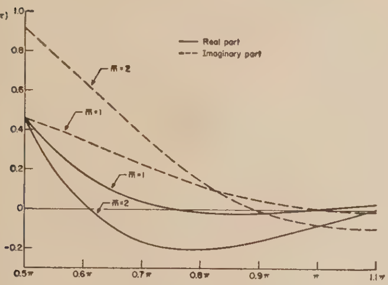

Fig. 2—Real and imaginary parts of $f(\omega\tau)$.

Table I, below, summarizes the results of a calculation of the real and imaginary parts of Z at $\omega\tau=0.8\pi$ for two arbitrary cases for a germanium structure. To get the actual impedance of an idealized three-dimensional structure, one must add to Z the extrinsic base resistance r_b'. Thus for values of $r_b'<96$ ohms, a negative real part wil be exhibited by the structure of Case I.

TABLE I
SEVERAL EXAMPLES OF Z COMPUTED FOR GERMANIUM

	Case I	Case II
Base resistivity n-type (ohm-cm)	2.5	0.35
Donor density (cm^{-3})	7×10^{14}	5×10^{15}
Avalanche breakdown (volts)	200	40
Collector bias (volts)	180	36
Avalanche multiplication factor m	3	3
Space-charge width W (cm)	2×10^{-3}	3.3×10^{-4}
Transit time τ (sec)	3×10^{-10}	5×10^{-11}
Frequency at which $\omega\tau=0.8\pi$ (kmc)	1.3	7.8
Bias current I_{dc} (ma)	0.6	2.5
Collector diameter (cm)	1.25×10^{-2}	5×10^{-3}
Negative resistance (ohms)	−96	−24
Capacitive reactance (ohms)	1500	160

There remains one additional point to investigate, namely, the effect of the modulation of the avalanche multiplication factor m by the varying collector voltage. Since m is voltage dependent, an additional alternating component of space-charge current will be generated at the collector junction by the interaction of the bias current I_{dc} and the time-varying m. It can be shown rather straightforwardly that this contributes a term to Z given by

$$Z_{\text{multiple}} = \frac{W^4 I_{\text{dc}}\left(\frac{dm}{dV}\right)}{\epsilon^2 v^2 A^2}\,\frac{(\exp i\omega\tau - 1)}{i(\omega\tau)^3}. \quad (6)$$

This term, however, contributes a positive real part at $\omega\tau=0.8\pi$. Putting in numbers for the two examples illustrated previously, we obtain real parts of 33 ohms and 20 ohms for Cases I and II, respectively. It is seen that for the higher-frequency example, the positive resistance becomes rather large and almost compensates the calculated negative resistance.

It should be mentioned at this point that one may use, however, only Z_{multiple} of (6) in a sample in which the space-charge boundary is not allowed to oscillate. Such a case is practically found in diffused base transistors. Then, $\omega\tau$ has to be chosen to lie in a range between π and 2π. For a given current level, the amount of negative resistance obtainable is smaller than the values quoted in Table I.

DISCUSSION

It appears entirely possible to obtain a negative resistance at microwave frequencies with transistor-like structures using a combination of avalanche multiplication and transit-time effects. It is quite feasible in practice to realize low enough extrinsic base resistances which will not mask the calculated negative resistance effect. The carrier diffusion time through the neutral part of the base region is unimportant in the proposed device.

The required dc power levels, because of the rather high collector bias voltages needed (near avalanche breakdown) and relatively large currents, are of the order of a fraction of a watt for the examples cited. Provisions for rapid heat dissipation are therefore required. A decrease in this power requirement can be had, of course, by a reduction in the area, but only at the expense of a higher impedance level. For one of the examples discussed, Case I, a desirable impedance level was attained at 1300 mc with a collector diameter of 1.25×10^{-2} cm (5 mils). Higher-frequency units naturally require smaller diameters.

The use of avalanche multiplication unfortunately restricts the allowable voltage amplitude at the collector for linear operation. In addition, the avalanche mechanism is known to introduce excess noise. It has also been assumed that avalanche multiplication has a build-up time shorter than the discussed inverse frequencies.

Charge Analysis of Transistor Operation*

Beaufoy and Sparkes[1] have pointed out the usefulness of the charge concept in the analysis of transistor operation. One of the principle virtues of this method is that the time-dependent behavior of the transistor can be calculated from a knowledge of the dc properties of the device. In this note, we give a more general derivation of the basic equation used in charge analysis.

Consider a neutral region where n is the density of excess carriers of either sign in that region. Continuity requires

$$-\nabla\cdot J_n = \frac{n}{\tau} + \frac{\partial n}{\partial t} \quad (1)$$

where J_n is the particle current density and τ^{-1} is the recombination rate. Integrating (1) over the volume of the region, and assuming τ is constant in the region, we have

$$-\int \nabla\cdot J_n dv = \frac{N}{\tau} + \frac{\partial N}{\partial t} \quad (2)$$

where $N=\int n\, dv$ is the total number of excess carriers of a given sign in the region. By Gauss' theorem we have

$$\Delta I = \frac{N}{\tau} + \frac{\partial N}{\partial t} \quad (3)$$

where ΔI is the net particle current of a given type into the region. Multiplying through by q, the electronic charge, we finally have

$$q\Delta I = \frac{Q}{\tau} + \frac{\partial Q}{\partial t} \quad (4)$$

where $Q=qN$ is the total excess charge of either type in the region. Eq. (4) is the basic equation used in charge analysis. It is dependent only on the recombination model used and is independent of *any* of the other details of the region such as geometry, aiding or retarding fields, conductivity modulation, etc. Since the region is neutral, we may consider either majority or minority carrier flow at our convenience.

Under dc conditions, the charge in the base is given by

$$\frac{Q}{\tau} = \frac{1-\beta}{\beta} I_c = \gamma(1-\beta)I_e = \frac{\gamma(1-\beta)}{1-\alpha} I_B$$

where β is the base transport factor and γ the emitter efficiency. Defining the transit time[2] as the ratio of base charge to collector current, we have

$$\tau_t = \frac{(1-\beta)\tau}{\beta}.$$

[1] R. Beaufoy and J. J. Sparkes, "The junction transistor as a charge-controlled device." *ATE J.*, vol. 13, pp. 3–20, October, 1957; also in PROC. IRE, vol. 45, 1740–42, December, 1957. For a discussion of charge control in various devices, see E. O. Johnson and A. Rose. "Simple general analysis of amplifier devices with emitter, control, and collector junctions," PROC. IRE, vol. 47, pp. 407–418; March, 1959.

[2] L. J. Varnerin, "Stored charge method of transistor base transit analysis" PROC. IRE, vol. 47, pp. 523–527; April, 1959.

As an example of the charge method of analysis, we calculate the transient response of a grounded emitter transistor to a step in base current. For simplicity, we neglect the charging of the collector capacitance. We then have

$$q\Delta I = I_B - (1-\gamma)I_e = \gamma I_B - (1-\gamma)I_c$$
$$= \frac{Q}{\tau} + \frac{\partial Q}{\partial t}. \quad (5)$$

At dc, $Q=\tau_t I_c$. We assume that $Q(t)=\tau_t I_c(t)$ at all times; *i.e.*, the collector current is proportional to the total charge in the base and is not dependent upon its distribution.

Then (5) becomes

$$\left(\frac{\alpha}{1-\alpha}\right) I_B = I_c + \frac{1}{\omega}\frac{\partial I_c}{\partial t} \quad (6)$$

where

$$\omega = \frac{1-\alpha}{(1-\beta)\tau} = \frac{1-\alpha}{\beta\tau_t}.$$

For $I_c(o)=0$, we have

$$I_c(t) = \left(\frac{\alpha}{1-\alpha}\right) I_B(1-e^{-\omega t}).$$

This agrees with the usual expression where the delay time, t^* has been neglected. By this treatment, however, we see that reducing the emitter efficiency is equivalent to a feedback that reduces the gain, but increases the frequency response, of a grounded emitter transistor.

Determination of the Orbit of an Artificial Satellite*

Two recent letters have considered the determination of the orbit of an artificial satellite by means of multi-station Doppler tracking systems. In the first,[1] a system was indicated which was independent of the initial ranges, and could therefore be utilized to acquire as well as track vehicles in space, without previous position information. In the second,[2] it was pointed out that such a system would be open and require iteration, unless one relation in addition to the Doppler equations was obtained. This follows immediately from the fundamental relations for n stations and m successive time intervals:

$$\Delta R_{ij} = R_{i1} - R_{ij} \quad i = 1, \cdots, n \quad (1)$$
$$j = 1, \cdots, m$$

where the R_{ij} are the slant ranges, the ΔR_{ij} are the range increments, obtained from the Doppler data, and $R_{i1}=R_i$ are the initial ranges. Eq. (1) will result in $n-1$ equations in n unknowns. This clearly shows the need for an outside condition on the ranges.

As observed by Carrara, Checcacci and Ronchi, any of the R_{i1} may be expressed in terms of the remaining initial ranges; thus, one initial range in (1) may be expressed as a function of the other $n-1$ initial ranges. Recent work in this laboratory,[3,4] based upon these observations, has resulted in a solution of (1) for the ranges. The result derives from the existence of a geometrical relation among ranges to four stations in an arbitrary configuration in a common ground plane from a point in space.

The work may be outlined as follows. Writing the equations for four stations arranged in a cross as

$$(x_j \pm a)^2 + y_j^2 + z_j^2 = R^2_{ij}, \; i = 1, 2 \quad (2)$$
$$j = 1, 2, 3, \cdots$$

$$x_j^2 + (y_j \pm a)^2 + z_j^2 = R^2_{ij}, \; i = 3, 4 \quad (3)$$
$$j = 1, 2, 3, \cdots$$

and combining (2) and (3), one obtains the geometrical property

$$R_{1j}^2 + R_{2j}^2 = R_{3j}^2 + R_{4j}^2. \quad (4)$$

Since this is a purely geometrical relation, it holds for any j. As the difference of any two successive time-dependent values of any R_{ij} is equal to a range increment, proportional to the Doppler data obtained during the interval, one can write, for four successive observations:

$$(R_1 + \Delta R_{1j})^2 + (R_2 + \Delta R_{2j})^2 =$$
$$(R_3 + \Delta R_{3j})^2 + (R_4 + \Delta R_{4j})^2$$
$$j = 1, 2, 3, 4. \quad (5)$$

These may be linearized by use of (4); the resulting equation may be solved for the R_i and, with these, the succeeding ranges are obtained from (1). For a particular j any three of the four R_{ij} will serve to find the coordinates, x_j, y_j, z_j from (2) and (3). The Jacobian of this transformation yields a criterion for choosing the three R's resulting in the most accurate values of x_1, y_1, z_1.

These results may be generalized to include an arbitrary configuration of stations in the ground plane.

Radiation Damage and Transistor Life in Satellites*

Evidence in support of a region of intense nuclear radiation surrounding the earth became indisputable with the flight of the satellite 1958ϵ [1] on July 26, 1958, in the wake of 1958α and γ. Several theories of the origin and nature of the radiation were proposed, each of which would partially remove the ambiguity of the particles comprising the radiation and allow an estimate of radiation damage. Equal *a priori* weight was attached to theories suggesting protons [2] and electrons [3]. Further uncertainty arose when the results [4] of the Pioneer I flight (October 1958) were compared with previous results. The interpretational difficulties imposed by this mass of data were resolved for altitudes below 1200 km by the experiment reported by Freden and White [5]. In this experiment a stack of nuclear emulsions was carried to an altitude of 1230 km and recovered after the flight. Analysis of the tracks in the emulsions verified that protons comprise the inner charged particle radiation band and permitted an accurate estimate of the energy spectrum.

The Freden and White proton-energy spectrum has been employed as the basis for estimating the rate of atomic displacements produced in silicon and germanium transistors during exposure to the inner charged particle belt. Previous estimates [6], by failing to account properly for the importance of high energy protons in producing displacements, have yielded displacement production rates far lower than those obtained here. The present estimates are also in better agreement with the limited experimental data for radiation damage produced by high energy protons.

In calculations of radiation damage to semiconductors, *e.g.*, Si or Ge, the practice has been to consider atomic displacements only and to ignore all but the Rutherford-type energy losses of the incident particle and successive knock-on Si or Ge atoms. The effect of inelastic $(n, n'\gamma)$ nuclear encounters has usually been dismissed on the grounds that the cross section for these events is relatively small at the energies usually considered and, moreover, is assumed to have a $1/E$ dependence, presumably well above their threshold.

Above 20 mev, however, nonelastic encounters (*e.g.*, neutron and charged particle emission) become of increasing importance [7]. Above 100 mev (which embraces almost 50 per cent of the radiation belt protons), nuclear disintegrations begin to dominate in importance over all other interactions, with increasing production of "stars" or small-scale spallation effects. Monte Carlo calculations based on high-energy "evaporation" models [8]–[17] and the phenomenological data obtained, mainly from analyses of nuclear emulsion events, indicate the importance of these phenomena in producing atomic displacements. These displacements occur not because of the knock-ons produced by incident protons,

---

* Received by the IRE, September 8, 1959.

but by virtue of the nuclear disintegrations in which they give rise to neutrons, protons, alphas, etc., of just about the right energy (5–20 mev) to produce a large number of atomic displacements by Rutherford collision within a thin Si or Ge wafer.

This is of importance, *a fortiori*, when it is contrasted with the small energy loss of an incident proton of 100 mev and more when it passes through the material in which the possibility of nuclear disintegrations has not been included. Smoluchowski reports on the results of irradiation of alkali halides with 100–400 mev protons [18] and concludes that at high energy the radiation effects caused by the secondary nucleons originating in the "inelastic" collisions are *at least* as important, if not more so, than those produced directly by elastic collisions of the incident protons.

For the reasons given, we have divided the problem into two parts:

1) $E<100$ mev,
2) $E>100$ mev.

1) $E<100$ mev

Each primary knock-on energy E produces $E_p/2E_d$ displacements [19], where E_d is the displacement energy which has been variously estimated as between 12–30 ev for Si and Ge [19], [20]. In calculating the total number of atomic displacements per target atom, the contributions of the primaries and successive knock-ons of lower order are summed separately; *i.e.*, N_d = primary displacements + progeny displacements. These relations are found [19], [20] to be:

$$N_d = \int_{E_d}^{E_{\max}} N_p dE_p + \int_{2E_d}^{E_{\max}} N_p \frac{E_p}{2E_d} dE_p$$

$$= \frac{CN_i}{E_iE_d}\left(1 + \frac{1}{2}\ln\frac{E_{\max}}{2E_d}\right);$$

where

$$C = \pi\left(\frac{Z_1Z_2e^2}{A_1 + A_2}\right)^2 A_1A_2$$

N_i = Incident flux,
E_i = Energy of incident particle,
N_d = Rate of atomic displacement.

The results of our calculations at an altitude of 1200 km appear in Table I. The estimates are conservative in view of the $1/E_i$ dependence assumed.

2) $E>100$ mev

The number of defects/cm³ produced by high-energy protons cannot be determined accurately because the exact mechanism of defect production by the nuclear fragments is not sufficiently well known to permit quantitative evaluation. We rely for the present, therefore, on experimental results obtained with NaCl and KCl [18], [22] which indicate that 1000 to 5000 defects per cm³ are formed by each incident proton per cm² above 100 mev. At an altitude of 1200 km, an omnidirectional flux of 560 protons/cm²/sec above 100 mev produces about 2–4×10⁶ defects/cm³/sec. Evidently, far from ignorable [6], each proton above 100 mev will form 1–5 times as many defects per cm³ as the lower energy (1–20 mev) particles usually considered important. Since the nonelastic collision cross section for "star" reactions varies approximately as $A^{2/3}$, the defect density from the high energy protons in Ge will be about twice that in Si. This is probably an underestimate since the fragments in the case of Ge will consist on the average of a higher mass with resultant increased ability to produce defects. Corresponding to the tabulated results for the lower energy proton component, the results for the protons above 100 mev at 1200 km are shown in Table II. The total damage rates, assuming a 12½ ev displacement energy are shown in Table III.

TABLE I

	N_d/proton/cm³		N_d/cm³-sec	
	E_d = 25 ev	E_d = 12½ ev	E_d = 25 ev	E_d = 12½ ev
Silicon	600	1200	.45×10⁶	.92×10⁶
Germanium	1000	2200	.75×10⁶	1.7 ×10⁶

TABLE II

	N_d/cm³-sec		Nd/proton/cm³	
	E_i = 25 ev	E_i = 12½ ev	E_i = 25 ev	E_i = 12½ ev
Silicon	0.85×10⁶	1.7×10⁶	1500	3000
Germanium	1.7 ×10⁶	3.4×10⁶	3000	6000

TABLE III

	N_d/proton/cm³	N_d/cm³-sec (1200 km)
Silicon	2000	2.6×10⁶
Germanium	4000	5.1×10⁶

In order to estimate transistor lifetime, a criterion of damage must be decided upon. There are a number of possibilities. Without discussing the relative merits of each, it seems somewhat more desirable to draw upon the vast quantity of data from reactor irradiation of semiconductors, because the local defect distribution produced by protons bears a closer similitude to fast neutron damage [23], and because of the availability of statistical data [24] for a large number of transistor types. Considerable variation of radiation sensitivity is found between different transistors which requires a certain arbitrariness in selecting a damage criterion, The data suggests setting neutron doses of $10^{12}n$/cm² for silicon devices and $10^{13}n$/cm² for germanium transistors. However, a critical radiation dose for a particular device may vary considerably from the criteria which were selected. The resulting defect densities using the theory described by Dienes and Vineyard [25] are:

Si, 5×10¹⁴ displacements/cm³;
Ge, 3.8×10¹⁵ displacements/cm³.

These defect densities are produced at 1200 km altitude in 9.2×10⁷ seconds (1060 days) in silicon and in 3.8×10⁸ seconds (4060 days) in germanium.

Using the flux-altitude relation obtained by Van Allen [1] and assuming that the Freden and White energy spectrum is independent of altitude, a curve of transistor lifetime vs equatorial (±25°) altitude can be constructed (see Fig. 1). The curves shown in Fig. 1 are necessarily limited to the inner radiation belt, for no accurate particle energy data for the outer belt have been obtained and are reliable only up to 1350 miles (2200 km), the highest data reported by Van Allen from 1958ε. The curves have been extrapolated through the anticipated maximum of the inner belt but are not supported by direct experimental measurement as are lower altitude data.

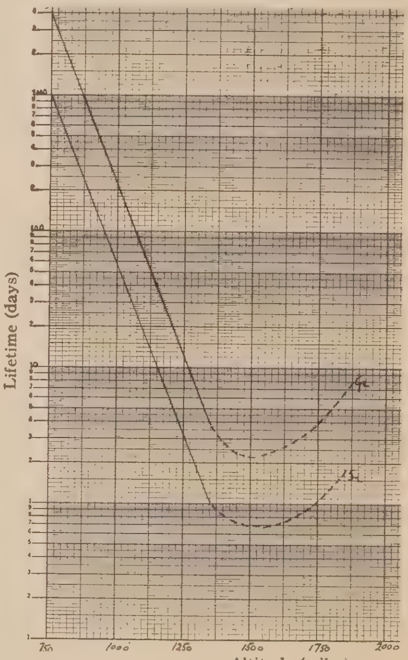

Fig. 1—Lifetime of semiconductors exposed in the inner equatorial (±25°) radiation belt as a function of altitude.

Clearly, semiconductor lifetime in satellites is an important consideration for altitudes in the 1500 mile (2500 km) range. If a one-year semiconductor life is desired, equatorial altitudes between 1000 and 2200 miles are unsuitable. Of course, many orbits will not be restricted solely to equatorial latitudes, nor is it reasonable to expect circular orbits. These considerations tend to increase the lifetime in orbit.

Frequently it is desirable to operate in a high radiation area and protect equipment from shielding. We have not considered the shielding question in detail, but preliminary considerations seem to rule out protection by shielding for present payloads. The range of a 100-mev proton is about 1.5 cm in Pb; since about half of the damage is produced by the protons above 100 mev, it is clear that several cm of Pb will be required to increase semiconductor lifetime significantly. Furthermore, since the total cross section we are discussing for nucleon-nucleon encounters is a few barns in usual shield materials and these cascade products are forward scattered in addition to other less preferentially radiated products, it appears that the use of thin shields may lead to an increase in damaging radiation. This shielding paradox is receiving further attention, particularly with respect to various shield materials and thicknesses.

Increasing the Dynamic Tracking Range of a Phase-Locked Loop*

The transient response and effective noise bandwidth of a phase-locked loop are related to the dynamic tracking range. However, the latter often can be adjusted without adversely affecting the first two. "Dynamic tracking range" refers to the range in frequency over which a phase-locked loop will track a signal of slowly-varying frequency (*i.e.*, Doppler shift) once the loop has locked on.

Consider the loop of Fig. 1. Fig. 1(a) shows a typical configuration, and Fig. 1(b) is the linear equivalent after Jaffe and Rechtin.[1] The low-frequency component out of the multiplier due to the signal is

$$K_m E_s E_0 \sin(\theta_1 - \theta_2)$$

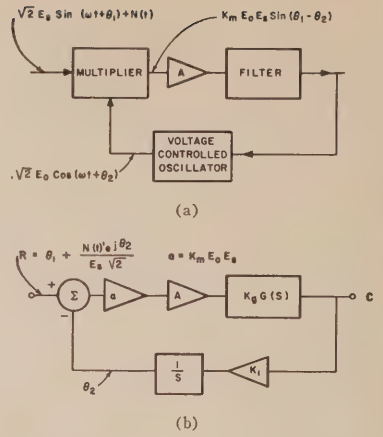
where K_m is a constant associated with the multiplier. Amplifier K_1 represents the change in frequency vs voltage (cps/volt). Let the filter have unity dc gain. Since the maximum output from the multiplier is $\pm K_m E_s E_0$, the maximum frequency change of the (dynamic tracking range) VCO for a signal of slowly-varying frequency (almost dc from the multiplier) is:

$$\Delta f_m = \pm K_m E_s E_0 A K_1. \qquad (1)$$

The generalized feedback equation for a negative sign on the summer is:

$$\frac{C(S)}{R(S)} = \frac{K_a F(S)}{1 + K_a K_b F(S) H(S)} \qquad (2)$$

where $K_a F(S)$ is the transfer function in the feed-forward path and $K_b H(S)$ is the transfer function in the feed-backward path. Writing $F(S)$ and $H(S)$ in terms of their poles and zeros shows that the poles of $H(S)$ and the zeros of $F(S)$ are the zeros of (2). The poles of $C(S)/R(S)$ may be found by solving for the roots of the equation:[2]



$\sqrt{2}$ E$_s$ Sin (ωt+θ_1)+N(t)
K$_m$ E$_0$ E$_s$ Sin (θ_1 - θ_2)
MULTIPLIER

1/S
K$_1$
θ_2
(b)

Fig. 1—(a) A phase-locked loop. (b) The linear equivalent $N(t)'$ is $N(t)$ translated from ω to a center frequency of zero.

$$K_a K_b H(S) F(S) = -1. \qquad (3)$$

For the loop of Fig. 1(b), (3) is

$$A K_m E_0 E_s K_g K_1 \frac{G(S)}{S} = -1 \qquad (4)$$

or

$$\left| \frac{G(S)}{S} \right|_{P_0} = \frac{1}{A K_m E_0 E_s K_g K_1}, \qquad (5)$$

and

$$\angle \frac{G(S)}{S} = 180° \qquad (6)$$

where

$$F(S) = G(S)$$

and

$$H(S) = \frac{1}{S}.$$

Then the closed loop will have one zero at the origin (due to $1/S$) and other zeros due to the zeros of $G(S)$.

If $K_g G(S)$ has unity dc gain,

$$\lim_{S \to 0} K_g \frac{\prod_j (S + a_j)}{\prod_i (S + b_i)} = \lim_{S \to 0} K_g G(S) = 1. \qquad (7)$$

Then

$$K_g = \frac{\prod_i b_i}{\prod_j a_j}. \qquad (8)$$

Assume that the transient response requires poles of $C(S)/R(S)$ at P_0 and P_0^* of Fig. 2. Eq. (6) is satisfied when

$$\sum_j \theta_j - \sum_{i=2}^{n} \phi_i - \phi_1 = \pi; \qquad (9)$$

n is the number of poles in $G(S)$, θ_j is the angle from the jth zero to P_0, and ϕ_i is the angle from the ith pole. The graphical

$K_g G(s) = \frac{C_2}{C_1+C_2}\left[\frac{S+\frac{1}{RC_2}}{S+\frac{1}{R(C_1+C_2)}}\right]$
$b = \frac{1}{R(C_1+C_2)}$; $a = \frac{1}{RC_2}$

Fig. 4—A typical $KgG(S)$.

method of finding the absolute magnitude gives[3]

$$\left|\frac{G(S)}{S}\right|_{P_0} = \frac{\prod_j r_{z_j}}{r_1 \prod_{i=2}^{n} r_{P_i}}. \tag{10}$$

Using (1), (8), and (10), (5) may be written:

$$AK_mE_0E_sK_1 = r_1 \frac{\prod_{i=2}^{n} \frac{r_{pi}}{b_i}}{\prod_j \frac{r_{zj}}{a_j}} = |\Delta f_m|. \tag{11}$$

If $G(S)$ is the simple lag network shown in Figs. 3 and 4, (11) is

$$|\Delta f_m| = r_1 \frac{\frac{r_2}{b}}{\frac{r_3}{a}}, \tag{12}$$

where a and b are as defined in Figs. 3 and 4.

If $b \ll a$, it is clearly seen that as b decreases, $|\Delta f_m|$ increases, allowing more or less independent adjustment. In theory, $|\Delta f_m|$ can be made arbitrarily large by making b arbitrarily small. Notice that the dynamic tracking range is directly proportional to r_1 which is a measure of the closed-loop bandwidth. This is in agreement with the observation that $|\Delta f_m|$ is often approximately the same as the loop bandwidth. A more complex filter may be required to shape the transient response, and for a multisection filter, (11) will give the value of $|\Delta f_m|$. With a slowly-varying signal frequency, these calculations should be very close to the value obtained in practice.

Combined AM and PM for a One-Sided Spectrum*

Chakrabarti[1] declares that he has not seen any report about the method of obtaining single-sideband modulation by simultaneous amplitude and phase modulation. The late Professor Barkhausen[2] pointed out the identity of single-sideband amplitude modulation with simultaneous amplitude and phase modulation, illustrating the theory with diagrams. He also discussed the matter in classroom lectures.

On the Large-Signal Aspect of the Broadband Multicavity Klystron Problem—Theory and Experiment*

In previous work by the author[1] and others,[2–5] methods have been devised (and applied to some problems) to calculate the performance of multicavity klystrons, namely, their broadband response and other characteristics under small signal conditions, including the effects of space-charge.

The present communication deals with an extension of the previous procedure which will be applicable at large signal levels. Although either an analog or a digital computer can be employed, we shall concern ourselves only with an analog solution and experimental verification in the case of a specific tube.

With the aid of the assumptions already indicated[6] one writes for a drift region

$$i_b = [i_a \cos\theta_{ab} + v_a jg \sin\theta_{ab}]e^{-i\psi}ab,$$
$$v_b = [v_a \cos\theta_{ab} + i_a jg^{-1} \sin\theta_{ab}]e^{-i\psi}ab \tag{1}$$

and, at a resonator gap, we have

$$i_b' = i_a' e^{-i\psi}g,$$

$$v_b' = \left[M^2Z(\omega)\,\frac{\eta}{u_0}\,i_a' + v_a'\right]e^{-i\psi}g \tag{2}$$

where the quantities i (i and i') and v (v and v') represent the ac current and ac velocity of the beam, respectively. Subscripts a and b denote the earlier and later planes transverse to the electron beam; *i.e.*, the beam is traveling from a to b.

$$g = -\frac{\omega I}{\omega_q u_0}.$$

I is the dc current, ω the operating angular frequency, u_0 the dc velocity of the beam and ω_q is the reduced plasma angular frequency.

$$\theta_{ab} = \frac{\omega_q d_{ab}}{u_0}.$$

d_{ab} = distance between planes a and b

$$\psi_{ab} = \frac{\omega d_{ab}}{u_0}.$$

M is the beam coupling coefficient, $Z(\omega)$ is the shunt impedance across the gap, and $\eta = e/m$ (charge to mass ratio) for an electron.

Eqs. (1) and (2) completely describe the behavior of any arrangement of cavities and drift spaces under the assumption of small signals. By a repeated application of (1) and (2), then, we can determine gain, power, bandwidth, etc., under small signal conditions.

Suppose, then, that an n-cavity klystron is considered. Let the ac voltage across the mth cavity be V_m; then

$$V_m = M_m Z_m i_m \tag{3}$$

where M_m, Z_m, and i_m represent the beam coupling coefficient, shunt impedance and the entering ac current at the mth gap.

One can also write

$$i_m = -j \sum_{k=1}^{m-1} \alpha_{km} V_k, \tag{4}$$

but for a phase factor, where,

$$\alpha_{km} = -M_k g \frac{\eta}{u_0} \sin\theta_{km} = M_k Y_0 \sin\theta_{km},$$

for instance,

$$\theta_{km} = \omega_q \frac{d_{km}}{u_0},$$

$$Y_0 = -\frac{g\eta}{u_0},$$

d_{km} = axial distance between cavities k and m. From (3) and (4) the ac voltage across cavity $n-1$ is

$$V_{n-1} = \left(\sum_{k=1}^{n-2} F_{k,n-1} V_k\right) e^{-i\psi}1, n-1,$$

where

$$F_{k,n-1} = -jM_{n-1}Z_{n-1}\alpha_{k,n-1}$$

$$\psi_{1,n-1} = \frac{\omega}{u_0} d_{1,n-1}. \tag{5}$$

If V_1 is the ac voltage exciting the input cavity and V_{n-1} is the ac voltage across the penultimate cavity, the following expressions for voltage gain can be written:

$$\frac{V_{n-1}}{V_1} = e^{-i\psi}1, n-1\,[F_{1,n-1} + F_{2,n-1}F_{12} + F_{3,n-1}(F_{23}F_{12} + F_{13}) + \cdots]. \tag{6}$$

[6] S. V. Yadavalli, *op. cit.*; these assumptions are inherent to the Llewellyn-Peterson equations in an appropriate form.

The large signal aspect is included as follows. Although the effects of large signals should be included even at an earlier stage in the solution of the problem, we assume here that small signal theory holds up to the computation of i_{n-1} (the current exciting the penultimate cavity). For the computation of the ac current exciting the nth (output) gap, the following approximation[7] is made

$$i_n = 2IJ_1(X_{n,n-1}), \qquad (7)$$

where J_1 is a Bessel function of the first kind of order one

$$X_{n,n-1} = \left(M_{n-1}\frac{\omega\eta V_{n-1}}{\omega_q u_0^2}\sin\theta_{n,n-1}\right). \qquad (8)$$

From a knowledge of i_n, (R/Q), and Q_n, it is not a difficult matter to calculate the power output and efficiency of the tube, since

$$V_n = M_n Z_n i_n,$$

$$P_{\text{out}} = \eta_c P_n = \frac{1}{2}\frac{|V_n|^2}{Z_n}\cdot\eta_c,$$

η_c being the output circuit efficiency. The electronic efficiency of the tube is $P_{\text{out}}/V_0 I$ where V_0 is the dc beam voltage.

The analogy with IF amplifier design has been discussed previously and will not be repeated here. Some details about the computer method of solution have been given elsewhere in literature.[8]

Employing the above model, computations have been made on an analog computer[9] to obtain the optimum bandwidth with a five-cavity X-band klystron. Fig. 1 shows the theoretical output power and the experimental verification of the same. The theoretical 3-db bandwidth is 59.0 mc, as compared with the experimental value of 57.0 mc. As can be seen, the agreement between theory and experiment is very good.

High Q Inductance Simulation*

An improvement which can be made to the pentode simulation of reactance,[1] particularly inductive reactance, is the elimination of the resistance component. This gives the simulated inductance an infinite Q. An advantage of such a simulator besides the high Q is that it has a smaller volume and lighter weight than an equivalent wire-wound iron-cored inductor. Circuits for simulation of components have been investigated by several authors and an extensive bibliography is contained in a recent survey by Cooperman and Franklin.[2]

The resistance component results from the plate resistance r_p and the resistance present in the plate load. This can be seen by referring to the equivalent current generator circuit of Fig. 1. The parallel combination of r_p and plate load resistance component is represented by R_{eq}. The choke prevents the ac input from being shorted out by the plate voltage power supply.

The input current can be expressed as follows:

$$i = i_p + e\left(\frac{1}{R_{\text{eq}}} + \frac{1}{sL} + sC\right). \qquad (1)$$

The turn-to-turn capacitance is represented by C. Tube interelectrode capacitances are neglected as is the large input blocking capacitor C_b.

To nullify any effect of the plate load on the input terminals, one component of the pentode excitation voltage e_g causes a cancellation current to flow. The other component provides excitation voltage of the correct phase so as to make the pentode draw reactive current from the input.

The pentode current can be represented by two components as follows:

$$i_p = g_m e_g = g_m e_{g1} + g_m e_{g2}. \qquad (2)$$

Substituting (2) into (1),

$$i = g_m e_{g1} + g_m e_{g2} + e\left(\frac{1}{R_{\text{eq}}} + \frac{1}{sL} + sC\right), \qquad (3)$$

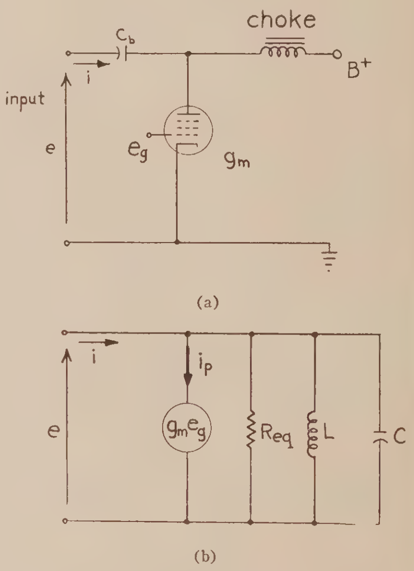
it is clear that to nullify the right hand term in (3), either one of the two components of i_p must be its negative; such as,

$$-g_m e_{g1} = e\left(\frac{1}{R_{\text{eq}}} + \frac{1}{sL} + sC\right).$$

Upon rearranging, this becomes:

$$\frac{e_{g1}}{e} = -\frac{1}{g_m}\left(\frac{1}{R_{\text{eq}}} + \frac{1}{sL} + sC\right). \qquad (4)$$

One method of providing this transfer function is through use of the circuit of Fig. 2.[3]



(a)

(b)

Fig. 1—Reactance tube circuit and its current generator equivalent network.

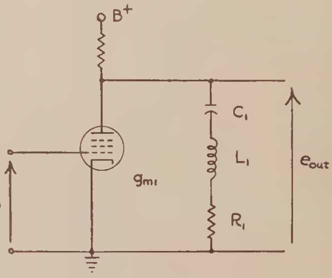


Fig. 2—Network to realize nullifying transfer function.

Here a series R-L-C circuit loads the plate of a pentode and provides a network transfer function of:

$$\frac{e_{\text{out}}}{e_{\text{in}}} = \frac{-g_{m1}}{\dfrac{1}{R_n} + \dfrac{1}{\dfrac{1}{sC_1} + sL_1 + R_1}}. \qquad (5)$$

The parallel combination of plate resistance and plate load resistance is represented by R_n.

[3] J. G. Truxal, "Control System Synthesis," McGraw-Hill Book Co., Inc., New York, N. Y., p. 187; 1955.

If

$$R_n \gg \left| R_1 + sL_1 + \frac{1}{sC_1} \right|$$

for frequencies of interest, (5) becomes

$$\frac{e_{\text{out}}}{e_{\text{in}}} \doteq - g_{m1} \left(R_1 + sL_1 + \frac{1}{sC_1} \right).$$

This expression is equivalent to (4) since the following dimensionless identities hold:

$$g_{m1}R_1 \equiv \frac{1}{g_m R_{\text{eq}}},$$

$$g_{m1}sL_1 \equiv \frac{sC}{g_m},$$

$$\frac{g_{m1}}{sC_1} \equiv \frac{1}{g_m sL}.$$

Upon connecting the network of Fig. 2, to provide excitation to the pentode, the input current to the simulator becomes

$$i = g_m e_{g2}.$$

In order that the input impedance be of the form sL_{in}, e_{g2} must lag e by 90° since

$$e_{g2} = \frac{e}{g_m s L_{\text{in}}}.$$

One method of obtaining e_{g2} from e is by use of an isolation amplifier and pentode loaded with a capacitor.

An improvement in the linearity of the simulator is obtained by using negative current feedback. The input current is sensed and the voltage amplified and fed back to the simulator pentode control grid. Second harmonic current is reduced substantially in this way.

The complete circuit is shown in Fig. 3.

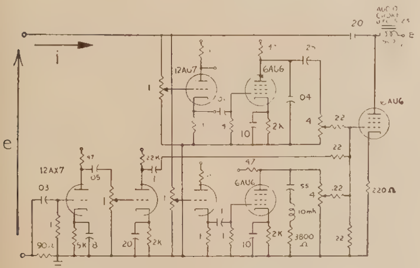

Fig. 3—Complete inductance simulator circuit.

Other kinds of two-terminal simulations are possible with this kind of circuit because of the flexibility allowed by having the input impedance a function of e_{g2} alone. One possibility is a negative inductance. It can be obtained simply by reversing the terminals at the output of the isolation amplifier in Fig. 3. Another is obtained when e_{g2} is obtained through two pentode-capacitor circuits in cascade. The input impedance then becomes proportional to $(sL)^2$.

The positive inductance simulator of Fig. 3 has a frequency range of 60 to 2000 cps, with an equivalent magnitude range of 28 to 2800 henries.

HF Noise Radiators in Ground Flashes of Tropical Lightning*

Previous analyses of this subject[1,2,3] ignore ground flashes because 1) they constitute less than 10 per cent of all discharges in the tropics,[4] and 2) the noise power involved at HF is not significantly different from that of cloud discharges. This letter gives the results of an analysis[5] for substantiating 2). It assumes information contained in Schonland[6] and Aiya.[1–7]

Results

A tropical ground flash lasts 0.2 second. It has four major discharges. Each such discharge consists of a leader stroke, a return stroke and M-components or M-type of discharge (it is the author's view that M-components are, in several respects, similar to the leader discharge with all its possible variations). The approximate time interval between successive major discharges, as measured between commencements of return strokes, is 0.04 second. A flash commences with a B field change which has significant pulsations at the beginning. In between the major discharges there is the J field change and, after the last major discharge, there is the F field change. The long-duration B, J and F field changes exhibit fluctuations which result in noise radiation of low power.

A typical tropical ground flash as an HF noise radiator is described in Table I. Type classification is based on the rms noise field strength corresponding to the average power received from an emission. The maximum or peak value of this quantity, A, arises from stage I of the leader discharge and can be calculated from (7) in Aiya.[2]

TABLE I

HF Noise Sources in Tropical Ground Flashes

Type number	rms field strength	Probable source of emission in the flash	Duration in Milli-seconds	Number of times it occurs in each flash	Total maximum duration of type in each flash	Remarks
I	$\frac{A}{16}$	1) Fluctuation of the B field change. 2) Fluctuation in the J field change. 3) Fluctuation in the F field change.	30 30 30	1 3 1	150	
II	$\frac{A}{8}$	1) Initial pulsive part of B field change. 2) M-components following each return stroke.	5 5	1 4	25	
III	$\frac{A}{4}$	Stage III or α portion of the first leader stroke	11	1	11	Of much shorter duration when height of cloud base is low
IV	A	Stage I of all leaders	1	4	4	
V	A	Stage II of first leader	2	1	2	Part or whole of it may not exist
VI	—	Return stroke. Behaves as a long vertical grounded aerial for HF with main lobe in polar diagram practically vertical and minor subsidiary lobes	1–2	4	8	Prominent reflected pulses from the ionosphere possible at short distances
VII	—	Stages II and III of second, third and fourth leaders or dart leaders	1	3	3	Radiation pattern similar to return stroke but with lower amplitudes

Departures from the description in Table I are to be expected because, even in the tropics, ground flashes show a greater variety than cloud discharges. This is probably due to 1) wide variations in the height of the cloud base above ground (it being very low in India after the regular monsoon has set in); 2) the general topography of the place, such as hills, high structures, etc., and electrical characteristics of the ground. When the height of the cloud base is low, some flashes may take the form of a continuous discharge to ground on which are superposed a very large number of M-components, and some may become one stroke flashes with a continuous discharge as described for the rest of the flash, and so on.

Noise Records

Recording of radiations from one complete cloud discharge requires very careful design of experiments, etc. It is not so for ground flashes because there is almost continuous radiation throughout the flash. Even when it is not visible, a ground flash is easier to identify as it radiates VLF noise also; however, precautions have to be taken in interpreting the records. First, there is the integrating effect of the recording gear be-

[7] S. V. C. Aiya, C. G. Khot, K. R. Phadke and C. K. Sane," Tropical thunderstorms as noise radiators," *J. Sci. Ind. Res.* (India), vol. 14B, pp. 361–376; August, 1955.

cause of its time constants. Secondly, close distance records depend on the height of the cloud base above ground, as most of the emissions originate from inside the cloud.

Extraneous noises always affect the records. There is always the noise from distant thunderstorms and, perhaps, galactic noise as a background. There are additional complications at close distances; there can be electrostatic fields arising from various causes; and furthermore, pulses from the return strokes and dart leaders may be received after ionospheric reflection along with M-components or J or F field change fluctuations. (It is not impossible to get such reflected pulses even when they are ruled out by MUF considerations, one of the several reasons for this being the abnormal ionization associated with thunderstorms.) The contributions from such extraneous noises are small and do not significantly affect the peak amplitude A. But, in other cases, what is recorded is the resultant amplitude deduced by applying the method of Friis.[8]

Power Per Flash

The rms field strength B per flash can be calculated from Table I in terms of A as follows:

B for a ground flash

$$= \sqrt{\frac{6 \cdot A^2 + 11 \cdot \frac{A^2}{16} + 25 \cdot \frac{A^2}{64} + 150 \cdot \frac{A^2}{256}}{200}} \tag{1}$$

$$= (0.2) \cdot A. \tag{2}$$

B for a cloud discharge as calculated earlier[3] is

$$\sqrt{\frac{4}{200}} \cdot A = (0.14) \cdot A. \tag{3}$$

B for a ground flash is about 3 db higher but, in actual records, it may even appear to be as much as 10 db higher due to extraneous contributions, etc., discussed. We conclude, therefore, that the HF noise powers involved in ground and cloud discharges are not very significantly different. Interference calculations will probably require either A or the quasi peak value, as described in Fig. 3 of Aiya.[2] The present analysis indicates that neither of these two quantities would be seriously affected by the subsidiary radiations in a ground flash.

Temperate Region Records

Horner and Clarke[9] and Horner[10] have published photographs of noise bursts in England at 11 mc with a 300-cps bandwidth. The photographs, their statements, and the fact that they have recorded VLF noise also simultaneously in most cases, indicate that their records are for ground flashes. There does not appear to be any feature in the photographs which is not covered by the discussion in this letter. It is, however, not unlikely that there would be some differences in the nature of atmospherics radiated by sources located in tropical and temperate regions but it would be premature to draw conclusions on the point at present.

Horner and Clarke[9] have measured the peak amplitudes on their records for distances of storm d, varying from 1 to 18 km. This peak amplitude corresponds to A and it can be calculated from (7) in Aiya.[2] For a space wave at 11 mc with 300-cps bandwidth, we get

$$A = (2.40) \cdot \frac{\sin \theta}{r} \ \mu\text{V/m} \tag{4}$$

where, θ = angle the direction of radiation makes with the axis of the dipole and r = distance of the source in 10^6 meters.

Close-distance calculations require the height of the cloud base, h, which is not given and has, therefore, to be estimated. As measured by them, d is the hypotenuse of a right-angled triangle of which H, the mean height of the radiator, is only one side. Since d could even be 1 km, it follows that H must be less than 1 km. Assuming $h = 0.3$ km, a not uncommon value, there would be no stage II for the leaders and stage I of first leader would start from cloud base and extend to 1 km above, *i.e.*, $H = 0.8$ km. For stage I of second leader, $H = 0.8 + 0.7 = 1.5$ km, and so on. (It may be pointed out that other possible assumptions for values of h will not materially change the calculated values.) Values from (4) and the measured values of Horner and Clarke are given in Table II. In the tropics, it is expected that measured values on individual storms would lie within ±3 db of the calculated values from (4) in the majority of cases. Hence, the agreement in Table II for temperate regions should be considered very satisfactory.

TABLE II
CALCULATED AND MEASURED VALUES OF PEAK AMPLITUDES IN μV/METER

Source distance in km	Leader number	Stage I height in km	Calculated value	Measured value of Horner and Clarke
1	First	0.8	1440	1400
3	First Second Third	0.8 1.5 2.2	771 693 545	varies from 900 to 550
1 to 18	—	—	1440 to 133	1500 to 50

Experimental Proof of Focusing at the Skip Distance by Backscatter Records*

For some years, the fieldstrength near the skip distance and its variation with time and space has been the subject of different calculations[1–3] and measurements,[4,5] but the focusing which was expected has not yet been proved in an unequivocal manner. However, this seems to be a result of technical rather than other difficulties.

For more than half a year, we have made backscatter records every day, on a fixed frequency of 16.65 mc. The film speed was low, so the time scale was rather narrow; with a pulse duration of 100 μsec we had a good resolution of distances.

In spite of the poor information we have with respect to ground scatter, it seems that backscatter observations are quite useful for our problem because focusing must be active twice whenever it occurs, *viz.*, on the direct as well as on the return way. In fact, clear focusing has been observed nearly every day for some time, often for many hours and for both magneto-ionic components [Fig. 1(a)].

The effect of focusing was less pronounced in summer than in winter. Also, the focusing phenomena observed at Breisach near Freiburg were less frequent and less important when observations were made in the direction of 250° (South-West) and especially 280° (West) than they were in the direction of 220° (South). These variations according to season and direction can be adequately explained by the following facts: the ionospheric turbulence should be greater in a northern direction; the disturbance of geometrical optics by the existence of Es layers must be more important in summer; and the defocusing effect of the refraction by the normal E layer[6] should be greater in summer.

Occasionally we found a clear focusing even for the two-hop rays (2F.); in these cases the difference of the skip distance for both components is twice that for 1F. This can be seen from Fig. 1(b).

Note with respect to the records that we use a 66-cps pulse recurrence frequency at the transmitter side, but 33 cps for the receiver sweep; only half of this sweep (corresponding to 2250 instead of 4500 km) is recorded, *viz.*, the delay between two successive transmitter pulses (dark lines at the lower and upper margin of the record). Thus we have an overlapping of two reflection patterns. Distinction of both patterns is made possible by switching the transmitter to 33 cps; this is done for a two-minute interval every quarter of an hour. The 1F. backscatter is the lower trace in Fig. 1(b) which has the quarter-hourly interruptions. It belongs to a pulse which was 1/66 second

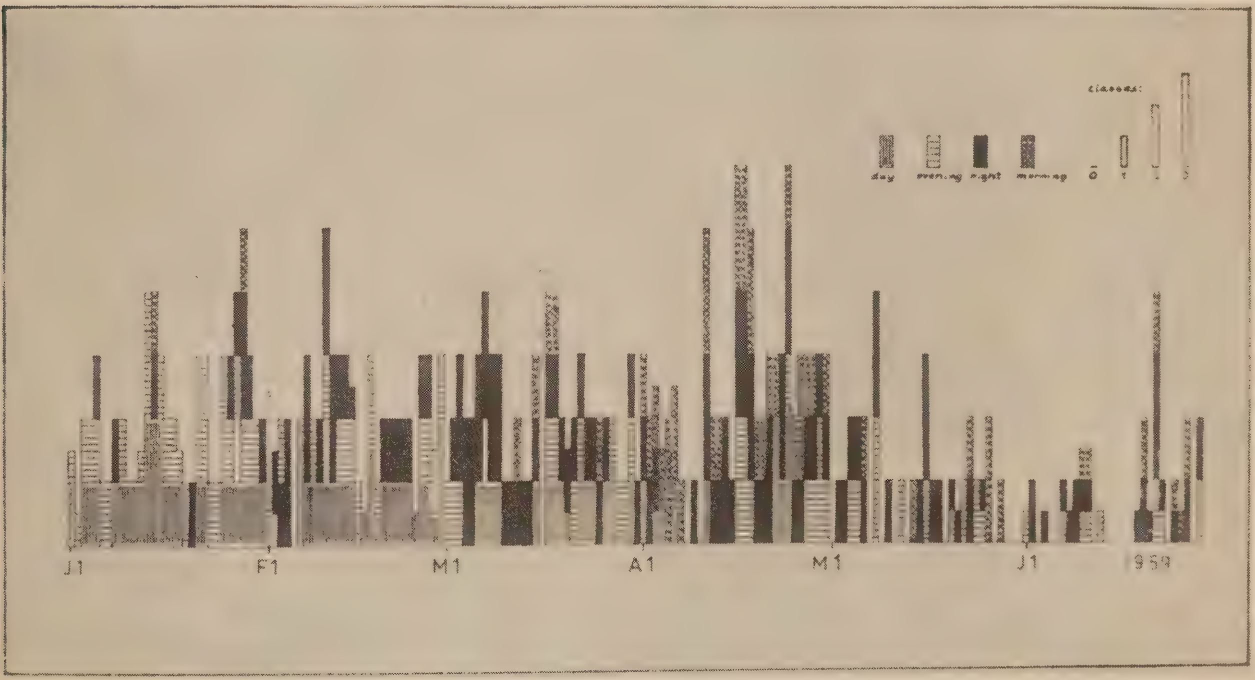

Fig. 2—Statistical results for the South and South-West directions.

below the lower black line; thus we must add 2250 km to the range as measured from this line. The 2F. backscatter is the upper trace in Fig. 1(b). The corresponding pulse is 2/66 second below the lower black line, so we must add 4500 km. In our example, the 2F. backscatter came from a distance of 5000 to 6000 km; this is about the distance from the United States to Freiburg.

In order to give a general view of the frequency of focusing, Fig. 2 gives day-to-day statistics for the last six months. Four periods of the day been represented separately (four colors). The importance of focusing has been classified in four grades: 0 = no focusing; 1 = weak focusing; 2 = both components distinctly visible at skip distance; 3 = lasting a long time and components distinctly visible. On our frequency, daytime focusing was only present in winter, nighttime focusing was most frequent in spring; the over-all importance decreased in summer.

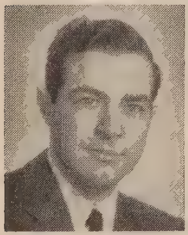
A. E. Anderson

Arthur E. Anderson was born in East Windsor, Conn., on June 2, 1923. He received the B.S.E.E. and M.S.E.E. degrees from the University of Connecticut, Storrs, in 1944 and 1951, respectively.

During World War II, he was a Radio-Radar Officer—Carrier Aircraft Service Units—in the USNR. From 1946 to 1951, he was an instructor in mathematics and electrical engineering at the University of Connecticut. Since 1951, he has been with the Westinghouse Research Laboratories, Pittsburgh, Pa., where he is presently manager of the Physics Project Laboratory. He has contributed to the development of the X-ray image intensifiers, direct view and signal generating visible image pickup tubes, color kinescopes, electroluminescent-ferroelectric field solid-state displays, high definition television and reduced bandwidth television systems.

Mr. Anderson is a member of Eta Kappa Nu, Tau Beta Pi, and Sigma Xi.

◆



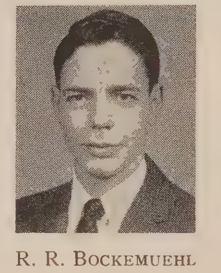
F. R. Arams

Frank R. Arams (S'44–A'49–SM'55) was born on October 18, 1925 in the Free City of Danzig. He received the B.S.E. degree in electrical engineering and mathematics from the University of Michigan, Ann Arbor, in 1947; the M.S. degree in applied physics from Harvard University, Cambridge, Mass., in 1948; and the M.S. degree in business management from Stevens Institute of Technology, Hoboken, N. J., in 1953. He is presently completing the requirements for the doctorate degree in electrical engineering at the Polytechnic Institute of Brooklyn, Brooklyn, N. Y. His dissertation concerns an investigation of new types of solid-state masers employing harmonic spin coupling effects.

During World War II, he served in the Army Signal Corps as communications chief of Radio Receiver Station WXH, Ketchikan, Alaska. He joined the Radio Corporation of America, Lancaster, Pa., in 1948, where he was project engineer on various development programs on microwave magnetrons, traveling-wave tubes, and plasma-filled cavities. From 1953 to 1956, he was employed at RCA Tube Division, Harrison, N. J., where he was in charge of the microwave tube application engineering group. In 1956, he joined the Airborne Instruments Laboratory, a division of Cutler-Hammer, Inc., Melville, L. I., N. Y., where he is presently associated with the department of applied electronics as Consultant, and is concerned with theoretical and experimental work on microwave solid-state devices, such as new types of solid-state maser amplifiers, microwave ferrite devices, etc. He is presently directing advanced programs in the microwave ferrite and traveling-wave maser fields.

Mr. Arams was a 1944 Donovan Scholar at the University of Michigan, and is a member of Tau Beta Pi, Eta Kappa Nu and the American Physical Society.

◆



R. R. Bockemuehl

Robert R. Bockemuehl was born in Omaha, Neb., on October 17, 1927. He received the B.S.E.E. degree from the University of Michigan, Ann Arbor, in 1952.

He has worked at the General Motors Research Laboratories, Warren, Mich. since 1952. Until 1958, his activities primarily included development of highly specialized instrumentation and control systems for use in scientific measurements and automotive testing. He is currently a Senior Research Engineer in the Physics Department of the General Motors Research Laboratories where he is engaged in basic and applied research in the field of solid-state electronic devices and compound semiconductor materials.

Mr. Bockemuehl is a member of Tau Beta Pi, Eta Kappa Nu and Phi Kappa Phi.

K. K. N. Chang

Kern K. N. Chang was born in Shanghai, China, on September 9, 1919. He received the B.S. degree from the National Central University, Nanking, China, in 1940, the M.S.E.E. degree from the University of Michigan, Ann Arbor, in 1948, and the D.E.E. degree from the Polytechnic Institute of Brooklyn, N. Y., in 1954.

From 1940 to 1945, he was associated with the Central Radio Manufacturing Works, Kunming, China, working on radio receivers. From 1945 to 1947, he was a radio instructor in the Office of Strategic Services, U. S. Army, China Theater. Since 1948, he has been at RCA Laboratories, Princeton, N. J., where he has been engaged in research on magnetrons, traveling-wave tubes, beam-focusing devices, and parametric and tunnel-diode devices.

Dr. Chang is a member of Sigma Xi.

◆

J. W. Coltman

John W. Coltman (SM'49–F'55) was born in Cleveland, Ohio, on July 19, 1915. He received the B.S. degree in physics from Case Institute of Technology, Cleveland, in 1937, and the Ph.D. degree from the University of Illinois, Urbana, in 1941.

He joined the Westinghouse Research Laboratories, Pittsburgh, Pa., in 1941, and spent the war years in research and development on microwave magnetrons. In 1946, he organized a group to undertake the development of a means to increase the brightness of fluoroscopic X-ray images. It was during the course of this work that he invented, with Fitz-Hugh Marshall, the scintillation counter. The project culminated in the first successful X-ray image amplifier, the Fluorex. Since 1949, he has been manager of the Electronics and Nuclear Physics Department of the Westinghouse Laboratories, guiding and participating in programs concerned with infrared and optical imaging, communications, underwater acoustics, microwaves, electron physics, solid-state physics, and nuclear physics.

Dr. Coltman has been a member of the Board of Editors and an Editorial Reviewer for the IRE, and is a Fellow of the American Physical Society and member of Tau Beta Pi and Sigma Xi.

◆

C. A. Desoer

Charles A. Desoer (S'50–A'53–SM'57) was born in Brussels, Belgium, in 1926. He received the radio engineer's degree from the University of Liége, Belgium, in 1949. He went to Massachusetts Institute of Technology, Cambridge, and obtained the D.Sc. degree in 1953. He joined the Bell Telephone Laboratories, where he worked in the transmission systems group, principally in the field of network theory. In 1958, he joined the Department of Electrical Engineering at the University of California, Berkeley. His main interest lies in systems and communication theory.

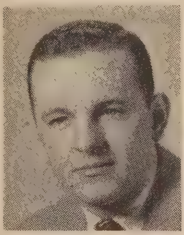
Dr. Desoer is a member of Sigma Xi.

J. H. Dietz

James H. Dietz (S'51–A'52–M'57), was born in Baltimore, Md., on January 18, 1927. He received the B.S. degree in physics from Loyola College, Baltimore, Md., in 1950 and the M.S.E.E. degree from the University of Pennsylvania, Philadelphia, in 1959.

From 1951 to 1953 he worked at the Radiation Laboratory of The Johns Hopkins University, Baltimore, where he was a member of a group engaged in the development of proximity-fuze circuits. Later, from 1953 to 1956, he was employed by the Bendix Radio Division, Towson, Md., working on the development of missile-guidance systems. He is presently a research associate on the staff of the Moore School of Electrical Engineering, University of Pennsylvania.

◆



G. H. Heilmeier

George H. Heilmeier (S'58) was born in Philadelphia, Pa., on May 22, 1936. He received the B.S.E.E. degree from the University of Pennsylvania, Philadelphia, in 1958, and is presently a candidate for the Doctor's degree at Princeton University, Princeton, N. J., under the sponsorship of RCA Laboratories.

Since 1958, he has been working in the general area of solid-state microwave dedevices with emphasis on distributed parametric structures, and he will receive the M.S. degree from Princeton in June, 1960, for his contributions in this area. He has also investigated the generation of millimeter waves by parametric methods.

Mr. Heilmeier is a member of Sigma Xi, Tau Beta Pi, and Eta Kappa Nu.

◆

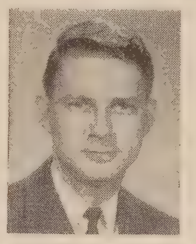
Y. H. Ku

Y. H. Ku (SM'53), was born in Wusih, China on December 24, 1902. He received the B.S. degree in 1925, the M.S. degree in 1926, and the D.Sc. degree in 1928, all from the Massachusetts Institute of Technology, Cambridge.

From 1932 to 1937, he was dean of Engineering, Tsing Hua University, Peiping, China, and from 1944 to 1945, he was president of Central University, Chungking, China. During World War II, he served as Vice-Minister of Education in the National Government of the Republic of China and later served as Commissioner of Education, Shanghai. He is presently a professor at the Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia.

Dr. Ku is a fellow of the AIEE and the Academia Sinica, and is an elected member of the General Assembly of the International Union of Theoretical and Applied Mechanics. He is also a member of Sigma Xi and Eta Kappa Nu.

◆



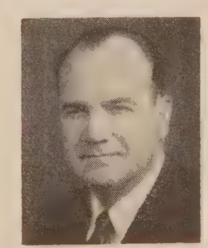
P. R. McIsaac

Paul R. McIsaac (A'59) was born on April 20, 1926, in Brooklyn, N. Y. He received the B.E.E. degree from Cornell University, Ithaca, N. Y., in February, 1949, after serving for two years in the U. S. Navy. He received the M.S.E. and Ph.D. degrees from the University of Michigan, Ann Arbor, in 1950 and 1954, respectively. During 1952, he was engaged in studying ferromagnetic metals at high frequencies at the University of Leeds, England.

From 1954 to 1959, he was employed by the Sperry Gyroscope Co., Great Neck, N. Y. where he worked on problems associated with the microwave circuits and the interaction theory for microwave tubes. At present, he is an associate professor of electrical engineering at Cornell University.

Dr. McIsaac is a member of Sigma Xi.

◆



W. W. Mumford

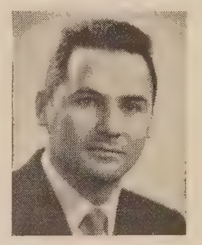
William W. Mumford (A'30–SM'46–F'52) was born in Vancouver, Wash., on June 17, 1905. He received the B.A. degree in 1930 from Willamette University, Salem, Ore., majoring in physics and mathematics. He served in the U. S. Coast Guard as a radio operator on the Cutter *Algonquin* in 1923 and 1924, and as a telegraph operator, clerk and manager with the Western Union Telegraph Company, in Washington and Oregon during the next two years. From 1928 to 1930, he was associated with the Oregon State Highway Commission Testing Laboratory. In 1930, he joined the Technical Staff of the Bell Telephone Laboratories with the Radio Research Department at Holmdel, N. J.

In 1953, he transferred to the Military Development Department of Bell Telephone Laboratories, Whippany, N. J., where he is now supervisor of a group engaged in the study of microwave radar problems and the exploratory development and exploitation of the latest techniques for improving noise figures of receivers.

He has worked on ultra-short-wave propagation and microwave components for radio relay systems and radars, and has studied the published literature concerning biological effects of microwaves as related to microwave radiation hazards. His contributions in the microwave field include the directional coupler, wideband coaxial-to-waveguide transducers, helix-to-waveguide transitions as used in the traveling-wave tube and the gas-discharge noise generator. These are covered in 31 published papers and 13 patents.

Mr. Mumford is a licensed Professional Engineer in New Jersey.

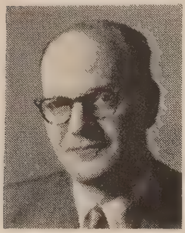
◆



S. Okwit

Seymour Okwit was born on August 31, 1929, in New York, N. Y. He received the B.S. degree in physics from Brooklyn College, Brooklyn, N. Y., and the M.S. degree in applied mathematics and physics from Adelphi College, Garden City, N. Y., in 1952 and 1958, respectively. He is presently doing work toward the doctoral degree in mathematical physics.

From 1952 to 1954, he was in the armed forces. He was assigned to the detection division of the Chemical and Radiological Laboratories of the Army Chemical Center, Edgewood, Md., where he did extensive development work on instrumentation for the detection and analysis of the poisonous "G" nerve gases. Detection instruments that he worked on include an infrared scanning system and a system utilizing microwave spectroscopy. From 1954 to 1955, he was associated with the radar department of Arma Corporation, where he was concerned with boresight studies on monopulse antennas. He joined the Airborne Instruments Laboratory, a division of Cutler-Hammer, Inc., Melville, L. I., N. Y., in November, 1955, as an engineer in the Department of Applied Electronics, where he was concerned with the design and development of RF, IF, and microwave components and systems. Since 1958 he has been responsible for, and has performed considerable theoretical and experimental work on, solid-state devices such as low-loss circulators, low-level ferrite limiters, and cavity and traveling-wave masers. Mr. Okwit is now a group leader in the applied electronics department at AIL, and is currently directing programs in the development of advanced solid-state devices including masser, parametric amplifiers, and novel ferrite components.



H. J. Prager

H. John Prager was born in Vienna, Austria, in 1915. He received the B.S.E.E. degree from the University of Vienna in 1938 and the M.S.E.E. degree from the University of Michigan, Ann Arbor, in 1940. From 1940 to 1942, he was associated with the Research Laboratory of the Detroit Edison Company, Detroit, Mich. In 1943, he joined the Electron Tube Division of RCA in Harrison, N. J., as a production engineer of small power and receiving tubes. In 1944, he transferred to the Receiving Tube Development Group where he served as Design Engineer, Technical Coordinator, and Unit Leader until 1959. His various assignments there included the design of several entertainment-type receiving tubes as well as premium industrial tubes, gas-filled tubes and UHF pencil tubes. From 1954 until 1959, he served as a member of the JETEC-12 Committee, and also was an Evening Instructor at the Newark College of Engineering, Newark, N. J. He is presently engaged at the RCA Laboratories, Princeton, N. J., working on semiconductor-microwave devices.

◆

A. W. Straiton

Archie W. Straiton (M'47–SM'49–F'43) was born in Arlington, Tex., on August 27, 1907. He received the B.S.E.E. degree in 1929, the M.A. degree in 1931, and the Ph.D. degree in 1939, all from The University of Texas, Austin.

He taught at Texas College of Arts and Industries, Kingsville, from 1931 to 1943. Since 1943, he has taught at The University of Texas, Austin, where he is now Professor of electrical engineering and Director of the Electrical Engineering Research Laboratory.

Dr. Straiton is a member of Eta Kappa Nu, Tau Beta Pi, Sigma Xi and the American Society for Engineering Eduction. He was a former member of the U.S.A. National Committee and Chairman of Commission II of URSI.

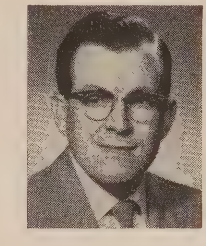
◆

C. W. Tolbert

Charles W. Tolbert (M'49–SM'55) was born in Homer, La., on August 28, 1920. He received the B.S. degree in general engineering from Texas College of Arts and Industries, Kingsville.

He was employed for two years by the National Geophysical Company, Dallas, Tex., before coming to the University of Texas, Austin, as an instructor in 1945. Shortly afterwards, he joined the staff of the University's Electrical Engineering Research Laboratory, where he has been responsible for much of the experiment program, and, in recent years, has been in charge of the millimeter studies.

◆



F. M. Turner

Franklin M. Turner (S'49–A'52–M'56) was born in Southington, Conn., on August 18, 1925. He received the A.A. degree from Grant Technical College, Del Paso Heights, Calif., in 1948. In 1950, he received the B.S. degree, and in 1951 the M.S.E.E. degree, both from Stanford University, Stanford Calif.

From 1951 to 1952, he studied microwave tubes as a research assistant with the Electronics Research Laboratory at Stanford University. In 1952, he became a staff member of this laboratory. He is currently a research associate with the Systems Techniques Laboratory, one of the five laboratories constituting the Stanford Electronics Laboratories at Stanford University. His present work is concerned with the development of new components and systems techniques related to electronic countermeasures.

Mr. Turner is an associate member of Sigma Xi.

◆

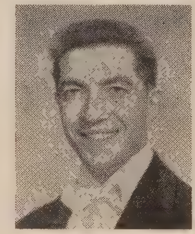
Chao C. Wang (A'43–SM'49–F'57) was born in Shanghai, China on October 20, 1914. He received the B.S.E.E. degree in 1936 from Chaio-Tung University, Shanghai, and the M.S. and Ph.D. degrees, both in radio communications, in 1938 and 1940, respectively, from Harvard University, Cambridge, Mass.

Since 1940, he has been engaged in microwave tube research and development. In 1940–1941, he studied vacuum tube manufacturing methods at the RCA Manufacturing Co., Harrison, N. J. During World War II, he worked on microwave tubes for radar applications at Westinghouse Electric Co., Bloomfield, N. J. Since that time he has worked in the investigation of problems in electron beam focusing by magnetic fields, and development of interaction and circuit theory of traveling-wave tubes. He has been Engineering Department Head for microwave tube research in the Sperry Electronic Tube Division, Sperry Gyroscope Co., Great Neck, N. Y., since 1956. In this capacity, he is also heading research in solid-state microwave electronics, thermionic emission, microwave gaseous plasma interaction, and computer development. He is also Victor Emanuel Professor at Cornell University, Ithaca, N. Y., for the Spring Term, 1960.

C. C. Wang

Dr. Wang is a member of the American Physical Society and the AAAS.

◆



A. A. Wolf

Alfred A. Wolf (S'49–A'49–M'55), was born on July 21, 1925 in Philadelphia, Pa. He received the B.S.E.E. degree from Drexel Institute of Technology, Philadelphia, Pa., in 1948, the M.S.E.E. degree from the Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, in 1954 and the Ph.D. degree from the University of Pennsylvania in 1958.

From 1949 to 1954, he was on the staff of the Anti Submarine Warfare Division of the Naval Air Development Center. Then, from 1954 to 1959, he was associated with the Moore School of Electrical Engineering of the University of Pennsylvania. He joined the Stromberg-Carlson Division of the General Dynamics Corp., Rochester, N. Y., in 1959, where he is at present applying his theory of nonlinear systems to the development of a sophisticated fault detection theory in which he relates statistically measured quantities at the output of the system being tested to deterministic quantities determining the configuration of the structure in response to white noise.

Dr. Wolf has principally been interested in the theory of nonlinear systems and related stochastic processes and has published a number of papers on these subjects.

Books

Probability and Statistics, Ulf Grenander, Ed.

Published (1959) by John Wiley and Sons, Inc., 440 Fourth Ave., N. Y. 16, N. Y. 434 pages. 6×9¼. $12.50.

This book, subtitled "The Harald Cramér Volume," is a collection of studies in probability and statistics which was presented to Professor Cramér in honor of his 65th birthday. It is thus a somewhat heterogeneous collection of both exposition and research by some of the most eminent probabilists and statisticians throughout the world. The papers range from theory of estimation, nonparametric inference, and design of experiments in the field of statistics to Markov chain theory and Brownian motion in the fields of probability and stochastic processes.

A more exact view of the contents of this volume can be conveyed by listing the authors and titles: T. W. Anderson—Some Scaling Models and Estimation Procedures in the Latent Class Model; M. S. Bartlett—The Impact of Stochastic Process Theory on Statistics; J. L. Doob—A Markov Chain Theorem; G. Elfving—Design of Linear Experiments; W. Feller—On Combinatorial Methods in Fluctuation Theory; E. Fix, J. L. Hodges and E. L. Lehmann—The Restricted Chi-Square Test; U. Grenander—Some Non-Linear Problems in Probability Theory; M. Kac—Some Remarks on Stable Processes with Independent Increments; D. G. Kendall—Unitary Dilations of Markov Transition Operators, and the Corresponding Integral Representations for Transition-Probability Matrices; P. Lévy—Construction du Processus de W. Feller et H. P. McKean en Partant du Mouvement Brownien; P. Masani—Cramér's Theorem on Monotone Matrix-Valued Functions and the Wold Decomposition; P. Masani and N. Wiener—Non-Linear Prediction; J. Neyman—Optimal Asymptotic Tests of Composite Statistical Hypotheses; H. Robbins—Sequential Estimation of the Mean of a Normal Population; M. Rosenblatt—Statistical Analysis of Stochastic Processes with Stationary Residuals; C. O. Segerdahl—A Survey of Results in the Collective Theory of Risk; J. W. Tukey—An Introduction to the Measurement of Spectra; S. S. Wilks—Nonparametric Statistical Inference; H. Wold—Ends and Means in Econometric Model Building.

These collected papers fill 434 pages and represent a most interesting cross section of modern probability and statistics. The articles are carefully written and the authors have supplied excellent references to each of the topics, many of which were advanced by Cramér's researches.

Although this book was not written specifically by and for members of the engineering profession but rather by and for probabilists and statisticians, it will serve as a source of valuable material, especially to those engineers conducting investigations involving stochastic processes. For example, the papers by Bartlett, Kac, Lévy, Rosenblatt and Tukey will be of particular interest. The printing is excellent and great credit is due Ulf Grenander for his excellent work as editor. Thanks also should be given to John Wiley and Sons for publishing "The Harold Cramér Volume" during Professor Cramér's lifetime.

Materials and Techniques for Electron Tubes, by Walter H. Kohl

Published (1960) by Reinhold Publishing Corp., 430 Park Ave., N. Y. 22, N. Y. 603 pages+20 index pages+13 appendix pages+xvii paages. Illus. 6¼×9¼. $16.50.

"Materials and Techniques for Electron Tubes" is a revised and updated version of the former "Materials Technology for Electron Tubes" (1951) written as a reference book for tube engineers and scientists. Its seventeen chapters cover, in a remarkably complete manner, much of the vacuum tube materials work performed during the last decade. As stated by the author, "This . . . is not a textbook from which to learn first concepts, but it is a very useful reference book to be used in conjunction with other texts."

The book has chapters on glass, ceramic and mica materials. Metals are covered by chapters on carbon and graphite, iron and steels, copper, nickel, precious metals, tungsten, molybdenum, tantalum and niobium, and a chapter each on getters, brazing metals and cathode metals. Although materials application techniques are discussed throughout the various chapters of this book, individual chapters are devoted to glass-to-metal seals and ceramic-to-metal sealing. The latter chapter of forty-nine pages reflects the increasing importance of this type of seal to the tube industry and appears to be quite complete. The chapters on iron and steels, precious metals and getters are welcome additions. With the single exception of the chapter on Joining of Metals by Brazing, which has been condensed, all other chapters have been revised and greatly expanded.

As was the case in his earlier book, Dr. Kohl has compiled a comprehensive and valuable list of references for each of his chapters. Most of the reference material (nearly 1200 separate listings) has been published since 1952. Sufficient information is included in the references to permit one to locate the material quite easily.

The chapter on Precious Metals deals largely with the solution of grid emission problems and might well be expanded in a future edition. Similarly, the section on oxide-coated cathodes should be expanded, particularly with respect to the role of the nickel base alloys and the influence they have on cathode performance as a function of temperature, time, alloying elements, etc. A very good list of references is cited in this chapter. In general one might wish to see more information on the properties of materials at high temperatures in high vacuum; however, these data are very hard to locate, and in many cases the engineer or scientist must be guided by reported application experience.

The chapters on Ceramic-to-Metal Sealing and Tungsten are very well done and Table 12.1 entitled "Brazing Filler Metals for Electron Tubes," showing properties of 143 high temperature materials is an outstanding example of the factual information available throughout this book.

Dr. Kohl has written a very valuable comprehensive reference book which should be of great assistance not only to tube engineers but to others working with these materials as well.

Mathematics for Communication Engineers, by S. J. Cotton

Published (1959) by the Macmillan Co., 60 Fifth Ave., N. Y. 11, N. Y. 229 pages+5 index pages+x pages+10 answer pages. Bibliography at end of each chapter. Illus. 6¼×10. $7.50.

The preface starts "It would be justifiable for anyone to exclaim: 'Another textbook on mathematics!' Yet this book was started in answer to a request from a number of students to bridge a gap which certainly does exist." On the one side is the mathematician with his proofs, and on the other side is the communications engineer needing to use advanced mathematics in his work. The book bridges this gap by giving developments of the ideas of advanced mathematics without always giving a full proof. Enough is given to make the result seem reasonable, and the results, especially in the early chapters of the book, are given in such a way that the communications engineer will find this a good book to use as a reference.

The topics covered are Review of Calculus, Determinants, Infinite Series, Trigonometric Functions, Complex Functions, Further Integration and Differentation, Differential Equations Applied to Lines and Networks, Theory of Functions of a Complex Variable, Harmonic Analysis, Vector Analysis, Special Functions and Equations, and Probability and Statistics. Each chapter contains examples of the application of the mathematics to a problem in communication engineering. There are exercises at the end of each chapter, and further exercises at the end of the book. Answers to the exercises are also given, so the book is well suited to self-study.

The book is well written and should be a real help to both students and practicing engineers. Once in a while the reader will run into wording which must be carefully studied. For example, in line 3 on page 142, reference is made to "any point in the region." Does the author mean that the condition he is imposing must apply to *all* points in the region, or only to *one* point in the region?

In the statement of the Laplace Transform (page 174) the same functional notation is used for the time-domain function, $f(t)$, and for the p-domain function, $f(p)$. This may be a mistake in typesetting, with $F(p)$ having been intended to show that these two are different functions as well as having different variables.

Some topics, such as matrix theory and advanced algebra, are not included in the book, nor are there any tables of functions.

The book is a compact package, reasonable in cost, with much advanced mathematics useful to the communications engineer. It lives up to its title quite well.

Telemetering Systems, by Perry A. Borden and W. J. Mayo-Wells

Published (1959) by Reinhold Publishing Corp., 430 Park Ave., N. Y. 22, N. Y. 331 pages+11 index pages+6 appendix pages+ix pages. Illus. 6¼×9¼. $8.50.

The field of telemetry is a rapidly expanding one. However, there are very few books on this subject. This book is therefore a welcome one and represents a modernization of a previous book by Borden and Thynell. The authors have made a particular effort to unify the older fields of industrial telemetry with the modern developments having application to aircraft and missile testing. It is particularly valuable in setting forth the components and concepts of industrial telemetering which are covered in the chapters on current, voltage and position systems of telemetering. There is an extensive section on the FM/FM system of telemetering which has considerable application in the aircraft and missile testing field. This, however, has been covered under the heading of "Frequency Systems of Telemetering."

The recent PCM system of telemetering is to be found in the chapter on "Impulse (Pulse) Systems of Telemetering." Also included in these chapters are the other pulse systems such as PPM, PDM, PAM, and two less known systems called Pulse Delta Modulation and Pulse Multiple Modulation.

The book also covers methods of reducing data collected by the telemeter in the chapters on Coordinating, Totalizing, Computing, and Integrating. The selection and application of telemetering systems are covered in a rather general way.

The manner of dealing with the subject matter is basically descriptive with some discussion of circuit details and block diagram configurations. There is little treatment from an analytic point of view of the design of telemetering equipment, of the analysis of bandwidth requirements and signal-to-noise considerations, or of the effect of interfering signals. Such considerations, for example, have been included in the radio telemetering field by Nichols and Rauch in their book "Radio Telemetry."

The authors have succeeded in their attempt to show the relationships between the older telemetering concepts and modern practice. However, some readers may find some difficulty in locating some of the newer systems in the framework of classification used in this book. The book will be found valuable to people working in the field because of the many examples of ingenious earlier practice in telemetry and will help people entering this field to become acquainted with the nature of telemetering devices.

Modern Network Analysis, by F. M. Reza and Samuel Seely

Published (1959) by McGraw-Hill Book Co., Inc., 330 W. 42 St., N. Y. 36, N. Y. 361 pages+5 index pages+6 appendix pages+xi pages. Illus. 6¼×9¼. $10.00.

The objective of the authors in writing this book is to provide a link between available introductory texts (such as that of E. A. Guillemin and others) and the more mathematical works (of W. Cauer, R. M. Foster, and others). This text has been "classroom tested" and is intended for an advanced undergraduate or a first graduate course on the analysis and synthesis of linear networks. As is true of such texts, a considerable number of problems are given (with no answers).

The book is divided into three parts, the first of which comprises chapters on the complex s plane, matrices and determinates, network topology and equilibrium equations. Part II comprises three chapters devoted to application to two-port networks, image parameter and conventional filters, and linear systems with distributed parameters. The last, Part III, of the book comprises five chapters on the system functions of linear systems and their transient response to singularity functions, a brief review of Laplace transform theory, and realizability formulas in network synthesis.

The authors prefer to use the exponentially damped sinusoidal excitation e^{st} because the ensuing steady state response of a linear system differs from e^{st} only by multiplication by a complex quantity. They should have indicated, however, that a definable and separable steady state response can occur only for a nondamped sinusoidal excitation for which $s=jw$.

The chapter on linear algebra dealing with matrices and determinants is particularly useful as a body of formulas with applications. This also applies to the chapters on network topology and network equilibrium equations. A good description is given of the matric interrelationship among the six methods of analyzing two-port linear systems. It concludes with a review of the realizability criteria for linear systems from considerations of the energy functions using, in particular, the matrices described in the text.

The book is recommended to all students interested in network analysis.

Brooklyn, N. Y.

Introduction to Matrix Analysis, by Richard Bellman

Published (1960) by McGraw-Hill Book Company, Inc., 330 W. 42 St., N. Y. 36, N. Y. 301 pages+6 index pages+19 appendix pages+xx pages. 6¼×9¼. $10.00.

To a very large extent, modern electrical engineering science is based on the concept of linearity. This is particularly true in the field of "systems" as opposed to "components." As a result of historical accidents as well as of the parochial attitudes of engineering educators in the past, the "linear systems" field is at present dominated by the Laplace transform, to the virtual exclusion of any other tool. This is as unfortunate as it is unnecessary. The growth of mathematics during the last century has given rise to an impressive body of knowledge based on linearity, which is nowadays usually called "linear algebra and analysis." Crudely speaking, linear algebra is matrix theory, and linear analysis is that class of problems (and much more) which engineers at present usually treat by the Laplace transform.

In the preface, the author calls matrix theory "the arithmetic of higher mathematics." For a scientific worker who is willing to use nontrivial mathematics (pure or applied), continued study of matrix theory deserves the highest priority. The reviewer feels strongly that matrix theory, as yet greatly neglected, belongs to the core of the engineering science curriculum. The reasons are: matrix theory is a theory of *complexity*, very useful in dealing with large networks, digital computers, etc.—areas where the Laplace transform is not well suited to cope with practical problems; it provides the rudiments of abstract language and thinking, without which the results of modern mathematics cannot be utilized.

The distaste of many engineers for matrix methods may be the result of inadequate expositions. Too many books have been written with the purpose of "selling" matrix methods, by concentrating on this or that application. On the other hand, texts in pure mathematics are unsuitable for engineering instruction because of complete lack of applications. So it is especially fortunate that the author of this book is an active leader in the fields of analysis and dynamic systems and has been concerned for many years with the delicate interplay between theory and applications. Equally fortunate for electrical engineers is the choice of subject matter, which is closely related in many cases to current applied problems. [Additional volumes are promised in this Series on 1) computational methods (by G. Forsythe), 2) linear programming and combinatorics (by A. Hoffman) and 3) network theory (by L. Weinberg).]

The book consists of short, brisk chapters, the main theme being quadratic forms. An outline of the contents is as follows:

Chapter 1 deals with maxima and minima of functions of two variables from several points of view.

Chapter 2 introduces matrix notation, transpose, inner product, etc.

Chapter 3 defines eigenvalues and eigenvectors and then applies these concepts to the diagonalization of symmetric matrices with distinct eigenvalues.

Chapter 4 begins with a detailed discussion of the Gram-Schmidt orthonormalization process and then completes the problem of diagonalizing symmetric matrices including simultaneous reduction of quadratic forms.

Chapter 5 considers maximization of quadratic forms subject to linear constraints. There is an interesting digression on partitioned matrices.

Chapter 6 is a quick look at functions of matrices, in cases where the matrix is diagonalizable. The integral of the Gaussian distribution is computed. Among the many interesting exercises is the Sylvester interpolation formula (No. 33) which can be regarded as the generalization of the partial-fraction expansions used in the theory of the Laplace transform.

Chapter 7 is devoted to the Rayleigh coefficient, the Fischer-Courant variational description of characteristic roots, etc.

Chapter 8 is a nice collection of inequalities, some not well known, such as those based on the formula for the Gaussian integral.

Chapter 9 is a quick, readable exposition of the elementary ideas of dynamic programming, from the point of view of matrices and quadratic forms.

Chapter 10 is perhaps of greatest interest to electrical engineers. It is concerned with linear matrix differential equations. Too many people do not yet know that the solution of the matrix differential equation $dx/dt = Ax$ can be expressed in the form $(\exp At) \times (0)$, a formula which is simpler and yet more general than the corresponding expression by Laplace transforms. Theorem 6 of this chapter (which goes back to Lyapunov) makes it possible to determine the integrated square of transient responses by solving a set of linear algebraic equations—this is at present usually done by means of cumbersome tables.

Chapter 11 deals with explicit representations of matrices and matrix functions, Jordan canonic form, normal matrices, etc.

Chapter 12 is a very brief look at Kronecker sums and products—these are of interest in recent research in stability theory, random processes, etc.

Chapter 13 is a study of stability in linear systems, based mainly on the theorem of Lyapunov in Chapter 10. This is the modern approach to the Routh-Hurwitz criteria and deserves further serious study, particularly by control engineers.

Chapter 14 is concerned with Markov chains and processes from the matrix point of view.

Chapter 15 is an ultra-short (because so little is known) note on the theory of linear dynamic systems whose defining parameters change randomly with time.

Chapter 16 deals with matrices with positive elements, illustrating their significance by some typical problems from mathematical economics.

There are four appendixes; one dealing with the solution of linear algebraic equations, and the remaining three with somewhat advanced special topics in quadratic forms.

The problems and bibliographical comments should be singled out for special praise. The former, some frivolous, some straightforward, some important recent results or tricks, are highly educational for those who aim at mastery of the subject, but do not sidetrack the beginning student. The references include the "classical" papers, at least since the 1940's and are also very useful in getting started on new research.

This is a superb book and is warmly recommended. Its wealth of material and modern point of view should appeal to the specialist. As most of the exposition is elementary, it should be well received as a text for the classroom or self-study, at about the senior or first-year graduate level.

The Theory of Optimum Noise Immunity, by V. A. Kotel'nikov (translated from the Russian by R. A. Silverman)

Published (1959) by McGraw-Hill Book Co., Inc., 330 W. 42 St., N. Y. 36, N. Y. 140 pages+xi pages. Illus. $7\frac{1}{4}\times10\frac{1}{4}$. $7.50.

Vladimir Aleksandrovich Kotel'nikov is one of the few electronics engineers ever to be elected Academician in the Academy of Sciences of the U.S.S.R. In 1947 he published a doctoral dissertation which was subsequently republished in book form in Russian. R. A. Silverman's excellent translation of this Russian classic should be of interest to English speaking communications engineers for both technical and historical reasons.

Kotel'nikov deals with the problem of analyzing the performance of various communication systems in the presence of additive Gaussian noise. This performance is measured by minimum probability of error in the case of discrete messages and minimum mean square error in the continuous case. The organization of this little book is as neat and concise as Kotel'nikov's mathematics. Part I serves to set the framework of the problems considered and to sharpen the few mathematical tools used in the rest of the book. Part II then treats the transmission of discrete messages, Part III the transmission of a continuous parameter value and Part IV the transmission of continuous time functions. Each of the latter three parts is peppered with examples of the application of the general theory to special types of communication systems—AM, FM, PAM, PPM, SSB, etc.

At a time when the space lag is exciting so much comment, it is interesting to examine this volume with a view to the possible existence of a "communication theory lag." The framework within which Kotel'nikov solves his problems is one which we now call statistical decision theory. Statistical decision theory was developed in this country by Wald shortly before Kotel'nikov first published his results in 1947. It was eight years later, however, before Middleton and Van Meter became the first to apply Wald's ideas to communication problems in this country.

Two other Sputniks of note in this volume are the geometrical interpretation of signals and the analysis of nonwhite noise filtering problems by the use of inverse filters. The former was first published in this country by Shannon in 1949, the latter by Bode and Shannon in 1950.

It seems fair to say that at the present time there is no single major concept (with the possible exception of the material in section 9-2) in Kotel'nikov's work which is not known in this country. As noted above, this was not true as little as five years ago. This is not to say that the results have all been worked out in this country—they have not.

The Electric Arc, by J. M. Somerville

Published (1960) by John Wiley and Sons, Inc., 440 Fourth Ave., New York 16, N. Y. 134 pages+7 index pages+9 bibliography pages+ix pages. 38 figures. $4\frac{1}{4}\times6\frac{3}{4}$. $2.50.

The author of this interesting little book has made an important and useful addition to the Methuen series of monographs on physical subjects. Although the preface states that the monograph attempts to give a brief account of this " . . . well known, but by no means well understood, phenomenon" it really accomplishes much more. The various aspects selected for discussion are very well chosen and represent the most important aspects of our present knowledge of the subject. Clear physical interpretations are substituted for the extensive and detailed treatment of original sources. The figures are simplified, but present clearly the essential facts under consideration.

The first chapter is a brief introduction section that reviews the over-all characteristics of arcs. Following this, Part I covers the phenomena of "the stable arc" in two chapters. The first of these covers the principal phenomena and theory of the long column; such as the energy balance in a plasma in thermal equilibrium, the Gerdien (or vortex) arc, the column gradient over four decades of pressure, the column temperature over six decades of pressure, electron density, energy transfer, and radiation, use as light sources in lamps, and concluding with a short section on the possibility of thermonuclear reaction in arcs.

The second chapter of Part I (Chapter 3) contains a brief, authoritative treatment of the basic phenomena associated with arc electrodes. The best theories of the cathode spot are presented together with pertinent experimental data. Anode phenomena and electrode-vapor jets are discussed in short sections.

Part II (Chapters 4 and 5) is entitled "The Approach to the Stable Arc." The first chapter discusses the transient phenomena of the "spark" as it develops into a stable arc. Chapter 5 considers briefly the transition from a glow discharge to an arc, and the formation of an arc by separating current-carrying contacts.

The book concludes with a list of 186 important references, an author, and a subject index.

Professor Somerville's book will quickly and accurately orient the newcomer to the field with the best experimental and theoretical knowledge of the electric arc as it is now understood.

Sound in the Theatre, by Harold Burris-Meyer and Vincent Mallory

Published (1959) by Radio Magazines, Inc., Mineola, L. I., N. Y. 92 pages+3 index pages. Illus. $8\frac{1}{2}\times10\frac{1}{2}$. $10.00.

The authors of this book have pioneered in the use of modern equipment and techniques for sound control and special sound effects for drama and opera in live theatrical production. This book brings their experience to the neophyte, whether he is a theatrical person needing practical technical knowledge, or an experienced engineer making his first entrance into the complex artistic realm. After a brief summary of basic facts of acoustics, there are chapters on architecture and scenery, sources and pickup of sound, control techniques, systems, input equipment, output equipment, organization and planning, and installation and use. Much of the information is specific to theatrical productions which the authors have assisted. The book may leave the reader asking questions, but it is an interesting introduction to the borderline field between electrical engineering and the theatrical arts.

The Physics of Television, by Donald G. Fink and David M. Lutyens

Published (1960) by Doubleday and Company, Inc., 575 Madison Ave., N. Y. 22, N. Y. 153 pages+7 index pages. 44 figures. 4¼×7¼. paperbound. $0.95.

This is a very remarkable book. It attempts in 150 pages and with practically no mathematics to present the story of television to the layman, up to and including color.

It starts with the brain wave associated with thought and surveys various forms of transmission of that thought, starting from hand signals up; explaining the limitations of each form and why more sophistication is desirable. The description of the technique of coding and scanning for television is excellent.

The discussion of basic physics is well written and really tries to make things simple and understandable to the layman. To my mind it is too detailed and presents concepts too difficult for the reader. The concept of electron jumps of different energy content is a very difficult one (particularly without mathematics) and I believe could well be skipped. Assumptions are made that the reader is already familiar with a transformer and that he knows a spiral drawing represents a coil of wire or maybe a transformer winding. As an old-time teacher I know that interpretation of symbolic diagrams is not easy and requires both explanation and practice. It has the fastest discussion of alternating current this reviewer has ever seen.

It seemed to me when I read the book that it was much too conceptually complex for the average reader, even though beautifully organized and written. Although I believed that if anyone could achieve this aim the present authors could, I was about to dismiss it as another "experiment noble in purpose."

To confirm my judgment, I lent the book to a friend who had no physics except in high school some years ago. To show how wrong I was I received this note, "Many thanks for the chance to read this book. I will buy a copy and continue reading—think it is excellent."

Imagine my confusion!

Class D Citizens Radio, by Leo G. Sands

Published (1960) by Ziff-Davis Publishing Co., 1 Park Ave., N. Y. 16, N. Y. 133 pages+3 index pages +38 appendix pages+x pages. Illus. 6¼×9¼. $4.95.

According to this book, the FCC in mid-1959 was processing 5000 applications per month for Class D citizens radio station licenses. This extraordinary activity may give some idea of the popularity of this radio service whereby any United States citizen over 18 years of age may install and operate a two-way private radiotelephone in his car, plane, boat or camp, home, or office.

The book explains in essentially nontechnical language what this service is all about, how to get into it, how to buy and install and operate the equipment.

It is an excellent book for the radio engineer to recommend when he is asked to advise anyone on any aspect of the Class D portion of the so-called citizens radio spectrum. It is not a design book, nor a how-to-do-it book. It tells the reader what equipment is available, how much it costs, and the rules and regulations governing its use.

Millimicrosecond Pulse Techniques, by I. A. D. Lewis and F. H. Wells

Published (1960) by Pergamon Press, 122 E. 55 St., N. Y. 22, N. Y. 360 pages+3 index pages+1 bibliography page+29 reference pages+22 appendix pages. Illus. 5½×8¾. $8.50.

Since its original publication in 1954, this book has enjoyed great popularity among physicists and electronic engineers as a ready reference on fundamental aspects of electronics and networks in the millimicrosecond range. The text of this newest second edition has been considerably revised and abounds with the latest advances including a special treatment of transistor switching techniques. It is a very welcome addition to the International Series of Monographs on Electronics and Instrumentation. It is intended to cover, in the words of the authors, "developments in the theory and design of electronic circuits and devices for operation in the range of time intervals which lie between the province of microsecond pulse circuits and the realm of microwave devices."

Some idea of the scope of the book can be obtained from the headings of the eight chapters into which it is divided. These chapters are entitled, "Theoretical Introduction," "Transmission Lines," "Transformers," "Pulse Generators," "Amplifiers," "Cathode Ray Oscilloscopes," "Applications To Nuclear Physics," and "Miscellaneous Applications."

Under "Theoretical Introduction," the reader is briefly guided into the domain of circuit analysis involving both sinusoidally varying and pulse waveforms. Fourier's Theorem is illustrated, the method of Laplace Transforms elaborated upon, and the importance of approximations stressed. The chapter concludes with remarks on the handling of switching phenomena and circuits with distributed parameters. In the latter, phase distortion rather than amplitude distortion may well determine the useful bandwidth.

The chapter on "Transmission Lines" contains an extremely wide range of topics covering conventional distributed circuit analysis, effects of discontinuities, pulse shaping, and the influence of loss. Also, a very interesting treatment of helical delay lines is given in addition to limitations of lumped delay lines.

The role of distributed lines as pulse transformers is extensively described in the chapter on "Transformers" and includes an analysis of smooth tapered lines, the Gaussian line, the exponential line, and the linearly tapered coaxial line. It is followed by a compact description of special transformers composed of coaxial lines, such as the pulse inverter, stacked-line transformers, and a filament isolating transformer as well as an introduction to coupled-line transformers.

The treatment of "Pulse Generators" represents a remarkable review of the literature on diverse aspects dealing with basic concepts and principles. The major topics relate to discharge line type pulse generators, pulse generators employing secondary emission tubes, recycling pulse generators, attenuators, and pulse measuring equipments. The range includes microwave pulses.

The problem of amplifying pulses is considered under "Amplifiers" following a discussion of high-frequency limitations of conventional electron tubes and conventional circuits. Basic difficulties and inherent advantages are carefully described in connection with interstage coupling, cascade amplifiers, distributed amplifiers, and bandpass amplifiers, including traveling-wave tubes and the possibility of using modulated microwave carrier systems.

The introductory material in the chapter on "Cathode Ray Oscilloscopes" emphasizes transit-time limitations and methods for obtaining high deflection sensitivity. It is followed by selected topics relating to transient recording oscilloscopes, oscilloscopes for the display of recurrent waveforms, and oscilloscopes for recurrent pulses using pulse sampling techniques.

A detailed treatment of applications is contained in the chapter entitled "Applications to Nuclear Physics" and is continued in the last chapter on "Miscellaneous Applications." The first of these two chapters is devoted to measuring problems encountered in nuclear physics research and special mention is made of scintillation counters, spark counters, amplitude discriminators, fast scaling circuits, coincidence circuits, time interval measurement by integration methods, and recording oscilloscope measurements. The last chapter considers a number of other applications, mainly, pulse generators for narrow bandwidth radio receiver measurements, peculiarities of waveguide and cable testing, the Wamoscope, the measurement of time jitter in trains of video pulses, analysis of modulated electron beams and transistors in fast switching circuits.

The authors are to be commended for bringing to the attention of physicists and engineers the present day capabilities of pulse circuits. The bibliography of each chapter is very complete and many references are detailed enough to offer specific information as to their value. The text will definitely ease the task of all who seek to become informed about pulse techniques. It is an excellent contribution, one of the most balanced and most illuminating studies yet made of this complex field.

Scanning the Transactions

Human Factors in Electronics has become the 28th IRE Professional Group to commence publication of TRANSACTIONS, and its first issue starts off with a most provocative subject—man-computer symbiosis. Symbiosis is defined as a cooperative living together in intimate association of two dissimilar organisms. The hope is that in not too many years human brains and computing machines will be coupled together very tightly, and that the resulting partnership will think as no human brain has ever thought and process data in a way not approached by the information-handling machines we know today. In such a relationship the computer would no longer be confined to solving preformulated problems by means of predetermined programs, but would actively participate in the formulation of the very problems it must later solve and share, on a real-time basis, in the decision-making processes now performed by man alone. Man will still set the goals, formulate the hypotheses, determine the criteria and perform the evaluation, but the computing machine will do much of the routinizable work that must be done to prepare the way for insights and decisions. However, before the computer can enter into symbiotic association with man, man must first evolve a more sophisticated generation of computers with time-sharing capabilities, greatly improved memories and memory organization, a common man-machine language, and much improved input and output equipment. When these goals are reached—and they are within our eventual reach—man will be ready for what may prove to be intellectually the most creative and exciting chapter in the history of mankind. (J. C. R. Licklider, "Man-computer symbiosis," IRE TRANS. ON HUMAN FACTORS IN ELECTRONICS, March, 1960.)

Dual-unit transistors, reminiscent of multi-unit tubes, are making an entry into the semiconductor device field. A diode-triode transistor has been developed which consists of an alloyed *p-n* junction (diode unit) and an alloyed *p-n-p* junction (triode unit) constructed on one germanium pellet so that the *n*-type base region is common to both units. This construction provides direct connection between the diode and triode units and permits the use of fewer circuit components. The diode is intended for use as a detector and the triode as a Class A audio amplifier in a transistorized broadcast receiver. In addition to reducing the number of components re quired, the dual-unit transistor increases the detector efficiency of battery-operated receivers. (D. Thorne and R. V. Fournier, "Improvements in detection, gain-control, and audio-driver circuits of transistorized broadcast-band receivers," IRE TRANS. ON BROADCAST AND TELEVISIONS RECEIVERS, December, 1959.)

Research on research is an exciting and potentially fruitful new area of investigation which, it is hoped, will in time increase our understanding of and ability to manage the vital processes of Research, Development, and Engineering. It is a field that is in its early stages and the literature contributing to it is not yet readily accessible to the engineering manager—a void which the current issue of IRE TRANSACTIONS ON ENGINEERING MANAGEMENT makes a noteworthy effort to fill. In glancing through the papers in the issue one is struck by the fact that most of the authors are not engineers but rather are economists, sociologists, and operations researchers. Apparently, much of the initial motivation for doing "research on research" stems from an interest in economic factors, in social behavior, or simply in problems that are intriguing to analyze. One is also struck by the degree in which mathematical tools are being employed to analyze the affairs of humans. Thus one finds the authors speaking of such things as stochastic models, regression models, sets of sets, and logistic cubic functions in discussing the organization and operation of a research staff. Perhaps this is a sign that our understanding of the management process has progressed to a point where we are beginning to be able to formulate the problems to be solved. For before we can arrive at useful answers, we must first learn how to state the questions. (IRE TRANS. ON ENGINEERING MANAGEMENT, March, 1960.)

Active networks have a unique property: they can produce poles as well as zeros in the right half of the complex frequency plane. Such regenerative modes (exhibited in transient behavior as increasing exponentials) are essential for the operation of multivibrators, blocking oscillators, etc. In fact, the switching time, and thus the maximum repetition frequency, depends on the location of these right-half-plane natural frequencies. The farther away from the imaginary axis a regenerative mode is, the faster the operation possible. Now it turns out that if an RC network is used, the upper bound is fixed entirely by the physical active device and this upper bound can be easily computed directly from the active device. Not only is this extremely useful but it is satisfying to know tht it can actually be realized. (E. S. Kuh, "Regenerative modes of active networks," IRE TRANS. ON CIRCUIT THEORY, March, 1960.)

The powerful transistor. In view of the fact that transistors are essentially low-power devices, it is surprising to note how much power they can be called on to handle in switching applications. Germanium transistors having ratings up to 70 volts and 15 amperes having been introduced and developmental germanium devices with current-carrying capacities up to about 100 amperes have been made. More recently, silicon transistors and *n-p-n-p* devices (called Trinistors) have been developed which extend the power-handling capacity of semiconductor switches from the 1-kw limit of germanium Trinistors to the region of 10 kw. The extension of the current range of Trinistors, presently at 20 to 50 amperes, to 100 and 200 amperes is progressing rapidly. Indeed it appears feasible that power Trinistors may eventually be developed for use in inverter circuits operating in the 50 to 75 kva range. (H. W. Henkels and F. S. Stein, "Comparison of *n-p-n* transistors and *n-p-n-p* devices as twenty-ampere switches," IRE TRANS. ON ELECTRON DEVICES, January, 1960).

Abstracts of IRE Transactions

The following issues of TRANSACTIONS have recently been published, and are now available from the Institute of Radio Engineers, Inc., 1 East 79th Street, New York 21, N. Y. at the following prices. The contents of each issue and, where available, abstracts of technical papers are given below.

Automatic Control

Vol. AC-4, No. 2, November, 1959

Papers Reprinted from Part 4 of the 1959 IRE National Convention Record

On Adaptive Control Processes—R. Bellman and R. Kalaba (p. 1)

One of the most challenging areas in the field of automatic control is the design of automatic control devices that "learn" to improve their performance based upon experience, *i.e.*, that can *adapt* themselves to circumstances as they find them. The military and commercial implications of such devices are impressive, and interest in the two main areas of research in the field of control, the USA and the USSR, runs high. Unfortunately, though, both theory and construction of adaptive controllers are in their infancy, and some time may pass before they are commonplace. Nonetheless, development at this time of adequate theories of processes of this nature is essential.

The purpose of the paper is to show how the functional equation technique of a new mathematical discipline, dynamic programming, can be used in the formulation and solution of a variety of optimization problems concerning the design of adaptive devices. Although, occasionally, a solution in closed form can be obtained, in general, numerical solution via the use of high-speed digital computers is contemplated.

Discussed here are the closely allied problems of formulating adaptive control processes in precise mathematical terms and of presenting feasible computational algorithms for determining numerical solutions.

To illustrate the general concepts, consider a system which is governed by the inhomogeneous van der Pol equation

$$\ddot{x} + \mu(x^2 - 1)\dot{x} + x = r(t), \quad 0 \leq t \leq T,$$

where $r(t)$ is a random function whose statistical properties are only partially known to a feedback control device which seeks to keep the system near the unstable equilibrium state $x=0$, $\dot{x}=0$. It proposes to do this by selecting the value of μ as a function of the state of the system at time t, and the time t itself. By observing the random process $r(t)$, the controller may, with the passage of time, infer more and more concerning the statistical properties of the function $r(t)$ and thus may be expected to improve the quality of its control decisions. In this way the controller *adapts* itself to circumstances as it finds them. The process is thus an interesting example of adaptive control, and conceivably, with some immediate applications.

Lastly, some areas of this general domain requiring additional research are indicated.

A Dynamic Programming Approach to Adaptive Control Processes—M. Freimer (p. 10)

In many multi-stage decision processes we face the problem of dealing with random variables whose distributions are initially imperfectly known, but which become known with increasing accuracy as the process continues. In this paper the author shows how Dynamic Programming may be used to treat a class of such problems, which are currently called *adaptive processes*.

After discussing the general theory, the techniques are illustrated by a specific example. For this example simple computation algorithms are derived, which are typical of those obtained for the whole class of problems under consideration.

On the Optimum Synthesis of Multipole Control Systems in the Wiener Sense—H. C. Hsieh and C. T. Leondes (p. 16)

This paper is concerned with obtaining the optimum system in the Wiener sense for the multipole system shown in Fig. 1. Earlier literature has shown how to obtain the mean-square value of the error when the multipole system transfer function has been specified, but thus far no published work has shown how to solve the synthesis problem, in general, for this case. The principal reason that this problem has appeared to be impossible of analytic solution thus far for cross correlation between the inputs is based on the fact that the usual variational approach results in a set of untractable simultaneous integral equations involving many complicated cross products of the desired weighting functions and the variational functions.

The synthesis problem for the system of Fig. 1 is first solved for the case in which there is no correlation between the inputs to the various terminals. The result for the optimum weighting functions in this case is presented in (24), and the resultant mean-squared value of the error is shown in (25).

Following this, the far more complicated case of the synthesis problem when the inputs to all the various terminals are correlated is considered. In this case, a rather unique technique is utilized to avoid the difficulties inherent in the use of the usual variational techniques. Through the technique utilized in this paper, the usual set of untractable simultaneous integral equations is completely avoided, and instead a set of ordinary algebraic equations results. The set of equations for this case is shown in (64), and in matrix form in (65). The resultant solution for the optimum physically realizable transfer functions is shown in (77). It is also shown, as a check, that the solution for the case of correlated inputs reduces to the solution obtained for the case of uncorrelated inputs.

The paper then concludes with an illustrative example for the more complicated case of correlated inputs. The possibilities of applications of the results of this paper to such fields as the guidance and control of astronautical vehicles, military fire control systems, bombing navigation systems, process control systems, automatic milling machines, air traffic control, nuclear reactor control, etc., are fairly evident.

On Adaptive Control Systems—L. Braun, Jr. (p. 30)

An attempt is made in the paper to evolve a basic philosophy for adaptive control systems.

A method is described for determining the system impulse response from measurements of instantaneous system input and output. The impulse response is expanded in a Taylor series, to facilitate solution of the convolution integral.

From a knowledge of the impulse response and the system error, the necessary correction to the system forcing function is determined, in a manner similar to that used for determination of the impulse response.

The techniques developed are applied to two systems—one stable and one unstable. Curves of the results are presented.

Extension of Phase Plane Analysis to Quantized Systems—P. H. Ellis (p. 43)

The increasing applications of numerical control of processes have created a need for new methods of synthesis of control equipment. The method presented is applicable to systems commanded by discretely valued inputs, and processes whose outputs may be similarly quantized. Periodic sampling is not required. The most suitable sampling is by transmission of only significant data, as the new value obtained when the data are changed by a given increment. In certain cases, transmission of data by this means can be used to increase channel capacity. When the data are so quantized, the error signal is constrained to a finite number of discrete values, each of which may be associated with an area on the phase plane. Within each such area, the trajectories of any process subject to phase plane representation are a family of parallel curves. Thus, analytic synthesis may be simplified in the case of certain nonlinear processes. Graphical design is facilitated without requiring deduction of a mathematical representation of the process.

The method is illustrated by synthesis of several systems involving a simple linear process.

Simplified Method of Determining Transient Response from Frequency Response of Linear Networks and Systems—V. S. Levadi (p. 55)

Knowing the frequency response of a linear system, a method is presented for obtaining the time response of the system to an impulse, step, or ramp function input, without performing graphical integrations.

The transient response is of the form

$$f(t) = \sum_i A_i G(\omega_i t)$$

where a different function G is used to determine the response to each of the three types of input.

Tables of the functions $G(x)$ are provided. An example is given to illustrate the simplicity and accuracy of this method. The results are compared with the exact time response.

A New Method of Analysis of Sampled-Data Systems—A. Papoulis (p. 67)

In many sampled-data systems the sampling interval T is "small" and the response $r_s(t)$ closely approximates the response $r(t)$ of the continuous system; one is then interested in evaluating the difference $r_s(t) - r(t)$ for various values of T. In this paper this difference is given as a power series in T whose coefficients can easily be determined in terms of the continuous response; if one wants to estimate the size of T for $r_s(t)$ to equal $r(t)$ within a specified error, the first term of this expansion will give an adequate measure of the error and hence of the maximum permissible T. Furthermore, since the resulting series converges rapidly, the expansion provides a simple method of evaluating $r_s(t)$ for a given T.

The method is applied to a feedback system with a sampler; the singularities of the p-rational system function that gives the actual response at the sampling points, are obtained by a displacement of the singularities of the continuous system function.

Statistical Filter Theory for Time-Varying Systems—E. C. Stewart and G. L. Smith (p. 74)

The guidance and control accuracy of most aerodynamic and space vehicles is limited primarily by the noise disturbances which enter the guidance system. Present theory for the minimization of these noise effects does not take into account the forced kinematic time variations, such as is due to time-varying range, which occur in most guidance problems. Such time variations occur in interplanetary flight, satellite rendezvous, interception of missiles or bombers, and so forth. In this paper an analytical approach is presented for the optimization of systems which are forced both to be time varying and to operate with inputs contaminated with noise.

Two objectives are the establishment of the theoretical optimum performance and a method of synthesizing the optimum control system. Effects of restrictions on the capability of the output element in addition to the noise and the forced time variation are considered. Although an exact analytical solution of the problem does not appear feasible, it is shown how approximate solutions utilizing time-varying control systems can be found. The method is illustrated by a hypothetical example of a homing missile attacking a bomber.

On the Phase Plane Analysis of Nonlinear Time-Varying Systems—R. F. Whitbeck (p. 80)

A phase plane technique, which takes advantage of convenient relationships in other planes (for example, displacement versus time) to effect graphical solutions for a nonlinear time varying second order differential equation, is developed. Several special cases of this general second order equation are considered. The special case of most practical importance occurs when the differential equation is permitted to become piecewise linear. To demonstrate the simplicity of the technique, for the piecewise linear case, an example involving saturation in an inertially damped position servomechanism is given.

On the Use of Growing Harmonic Exponentials to Identify Static Nonlinear Operators—H. J. Lory, D. C. Lai and W. H. Huggins (p. 91)

The paper describes a method of obtaining a polynomial characteristic function for a nonlinear static system. This function,

$$F(x) = hx + mx^2 + dx^3,$$

is obtained by the application of a growing exponential $x = \exp(t)$ to the input of the system and the filtering of the output

$$h \exp(t) + m \exp(2t) + d \exp(3t),$$

into its separate components $h \exp(t)$, $m \exp(2t)$, and $d \exp(3t)$. The values of these three components at $t = 0$ are the polynomial coefficients h, m, and d respectively. The identification of systems not exactly describable by a cubic gives rise to an error minimization problem; the technique described in this paper minimizes the weighted mean-square error, with a weighting function $1/x$. This method is compared with the more widely known sinusoidal analysis of nonlinear systems. Experimental results are given.

A Parameter Tracking Servo for Adaptive Control Systems—M. Margolis and C. T. Leondes (p. 100)

This paper describes one very general approach to the design of adaptive control systems. The particular systems considered are process adaptive. The dynamic characteristics of the physical process are determined by the parameter tracking servo. The parameters thus determined are used to program the process' controller.

The parameter tracking servo is a closed loop self-adjusting system. It consists of the following elements; 1) the physical process, 2) the learning model, 3) the adjusting mechanism. The learning model and the physical process are subjected to the same input signals. Their outputs are compared and the resultant error is fed to the adjusting mechanism where some function of this error is used to adjust the parameters of the learning model.

The mechanism will continuously track the parameters of the physical process as they change with time in some unknown manner. The adjusting mechanism operates on an approximation to the method of steepest descent. These equations are derived for a first order process and the over-all system is analyzed. The equations describing the tracking servo's operation are both nonlinear and nonautonomous. System response as a function of input signal, gain, and error function are described analytically. Experimental results are included to demonstrate the validity of the analytic solutions.

Maximum Effort Control for Oscillatory Element—H. K. Knudsen (p. 112)

Maximum effort control is a method of achieving deadbeat response for a step input to an undamped second order element (two poles on the $j\omega$ axis of the s-plane) which is preceded by a saturating amplifier. This method of control supplies the maximum available energy to the element being controlled, by driving the amplifier to saturation whenever an error is present. The realization of a maximum effort control system for an oscillatory element is found through a phase plane analysis of the equations of motion of the oscillatory element. The control system topology is also found by the analysis of a phasor representation of the transients introduced in the oscillatory element by the output of the saturating amplifier.

The system was constructed to compare the experimental responses of step inputs and load disturbances, to the responses obtained from an idealized mathematical model of the system. The adaptability of the control system was tested by using it to control a damped oscillatory element.

The system described will be an aid in the design of the control system which will give optimum response for random inputs to an undamped second order element which is preceded by a saturating amplifier. It also provides a method of control for systems in which it is impossible to damp poles near the $j\omega$ axis.

Identification and Command Problems in Adaptive Systems—E. Mishkin and R. A. Haddad (p. 121)

In order to satisfy stringent performance requirements in a dynamic process, a computer is incorporated as a central element in the feedback loop. The computer performs the dual task of identifying or measuring the process' dynamics, and thence generating an appropriate command or actuating signal so as to satisfy the over-all specifications. The family of singularity functions (steps, ramps, confluent parabolas) is used as the command signal. The process' dynamics are monitored and identified by the computer without recourse to interrupting test signals such as periodic impulses or white noise. The stored energy term inherent in many measurement problems in continuous processes is accounted for in a novel manner.

Evaluating Residues and Coefficients in High Order Poles—D. Hazony and J. Riley (p. 132)

The powerful Laplace transform method for transient analysis by the partial fraction expansion technique has become quite popular in the fields of circuit and servo design. The theory of residues is usually used to find the coefficients of these fractions. The process is quite simple until second and higher order poles are included in the denominator. Previously, this has required a return to the calculus to find the additional coefficients required.

This paper discloses a simple technique for finding these additional coefficients by algebraic processes. As a result both manual and machine computation can be performed more easily. The technique is described and its mathematical basis is rigorously proven.

Coherent Optical Data Processing—L. J. Cutrona, E. N. Leith and L. J. Porcello (p. 137)

Coherent optical systems, which utilize the wave nature of light and the consequent diffraction phenomena, may often be used to supplement or even replace complex electronic equipment. Such systems are particularly adapted to the performance of certain linear mathematical operations, particularly those of an integral transform nature such as spectral analysis, convolution, auto- and cross-correlation, and matched filtering. The two-dimensional nature of optical systems, contrasted with the inherent one-dimensional nature of an electronic channel, allows a great reduction in equipment complexity for certain classes of operations.

This paper discusses the theory behind optical channels and filters as outlined above, and also illustrates simple multi-channel optical systems which can carry out representative operations.

Pole Determinations with Complex-Zero Inputs—J. A. Brussolo (p. 150)

A method for the determination of the characteristic pole locations in simple systems and components is discussed. The techniques introduced are extended to include more complex systems. The method consists of applying a signal to the system from a "complex-zero-generator" and then observing the system output response on an oscillograph. The system pole locations are determined when the system output goes through a null, which occurs when the zeros generated by the "complex-zero-generator" cancel the system poles. Tests on experimental systems indicate that the pole locations can be determined accurately and rapidly for a wide variety of systems.

For testing purposes, a "complex-zero-generator" was built using two square-wave generators with a timed delay between them. This generator gives a signal which can contain complex zeros anywhere in the s-plane. This signal is then applied to a number of systems containing several different relative pole orientations. The system outputs, as photographed on the oscillograph, are studied to develop rules and procedures to determine the pole locations. The rules are then applied to a number of "unknown" systems in order to determine their applicability and a study is made of the errors and limitations involved.

The results indicate that the method described is readily applicable to many systems and that, in many instances, the pole locations are determined more accurately and more rapidly than can be done through the use of a steady-state frequency analysis.

Random Noise with Bias Signals in Nonlinear Devices—G. S. Axelby (p. 167)

A number of investigations have been made in recent years about the transmission of Gaussian noise through nonlinear devices. In many cases, simplification or approximations were needed to make analytical solutions possible, and only zero-average Gaussian input signals were used when the results were applied to feedback control systems.

This paper presents a different approach to the problem of noise transmission through nonlinear single-valued elements. Basically, amplitudes removed by nonlinear saturation or deadzones are replaced by impulses in the amplitude distribution functions of the output signals, and the resulting first and second moments of the output distribution are computed to yield the average and rms value of the output signal. The solution may be found by graphical or mathematical integration, a visual representation of the phenomenon is obtained, and input signals with any distributions having non-zero average values may be considered.

It is shown that there is an equivalent transmission function or describing function for the average value of the noise, another for the rms value, and that one is a function of the other. Examples of the functions are given and the simpler functions with zero-average values are compared to the results obtained by other methods.

Finally, the application of the noise describing functions to feedback control systems is discussed. Theoretical results are compared with those obtained from analog simulations.

Nongyroscopic Inertial Reference—J. J. Klein (p. 182)

The space stabilizing cpability of a servo controlled nonrotating inertial mass is analyzed and its drift rate performance compared with a high precision gyroscope. The results indicate that the nongyroscopic inertial reference and guidance system exceeds the performance of gyroscopic systems by several orders of magnitude. It is shown that a servo system materially contributes to the drift accuracy in the nongyroscopic system but not in the gyroscopic system. The navigation errors of the discussed scheme are directly proportional to the accelerometer errors and, therefore, are inherently smaller than in an equivalent gyroscopic system.

Sampled Data Design by Log Chain Diagrams—M. P. Pastel and G. J. Thaler (p. 192)

The bilinear transformation

$$z = (1 + w)/(1 - w)$$

converts a z-transform function $G(z)$ of a sampled-data system into a new function $G(w)$, called the w-transform function, which is a rational function in variable w. This bilinear transformation maps the unit circle on the z-plane onto the imaginary axis of the w-plane. Consequently, it is now possible to draw log magnitude and phase diagrams readily against a frequency scale of the open-loop w-transform function of a sampled-data system by use of asymptotic techniques. Then, by use of a Nichols chart and correlation information available from continuous systems, it is possible to predict the approximate time domain performance. Design by modification of the open-loop transfer function can be made on the diagram in the same manner as employed for continuous systems on the Bode diagram. The resulting w-transform can be converted to its equivalent Laplace transform. The ratio of this transform function and the original Laplace transform function of the system's equipment gives the required compensator. Remote s-plane poles may have to be added to have the compensator physically realizable. Restricting the modifying w-plane poles to lie between (0) and (-1) permits the compensator to be realizable as an RC network.

Audio Applications of a Sheet-Beam Deflection Tube—J. N. Van Scoyoc (p. 3)

A number of unusual audio circuits have been developed which make use of a sheet-beam tube, type 6AR8. The 6AR8 tube is a miniature double-plate sheet-beam tube which incorporates a pair of balanced deflectors to direct the electron beam to either of the two plates and a control grid to vary the intensity of the beam.

This tube may be connected as a variable gain push-pull amplifier by connecting the input signal between the two deflectors and taking the output differentially between the two plates. When the tube is connected in this manner the amplifier gain is determined by the control grid voltage and may be varied over an 80 db range with negligible distortion.

The applications of this circuit include expansion and compression circuits, remote control of gain and mixing circuits, improved A.V.C. circuits and phase inversion. A number of these circuit arrangements are given in some detail and other applications are outlined.

A Drift-Free Direct-Coupled Amplifier Utilizing a Clipper-RC Feedback Loop—J. N. Van Scoyoc and E. S. Gordon (p. 8)

A unique drift-free direct-coupled amplifier has been developed employing a clipper and an RC integrating circuit in a feedback loop for stability. Equations are developed and computed and experimental curves are given for amplitude and phase-shift response as a function of frequency showing an extremely sharp power drop-off at the low end.

An existing application of this type of amplifier in an instrument for automatic counting and sizing of aerosol particles is described, demonstrating wide dynamic range and other advantageous features of the amplifier. Other potential applications of the Direct-Coupled Clipper-RC amplifier are given such as those of random pulse rate measurement, low level dc amplification using only a single-pole single-throw (SPST) chopper, and low level dc amplification of up to 20 concurrent inputs using a single amplifier and a slow-speed rotary switch.

Finally, a practical general purpose vacuum tube circuit of this amplifier type which was developed is described, giving data on pertinent characteristics such as low zero-drift, low noise, and high output capability.

The Application of the Voltage Variable Semiconductor Capacitor in Automatic Sweep Circuits and Signal-Seeking Receivers—J. Black (p. 16)

The basic method of automatic frequency sweep by charging a voltage variable capacitor is presented and the advantages over mechanically driven tuning capacitors are discussed.

The principle is extended by using the receiver automatic gain and/or frequency control for sweep control and station tracking, and practical circuits are shown embodying the principle.

Applications in the AM and FM fields, such as domestic and car radio receivers and television sets, are proposed.

The limitations of present devices and their effect on the application field are discussed.

An Analysis of a Transistorized Class "B" Vertical Deflection System—Z. Wiencek and J. E. Bridges (p. 20)

Considerations in Transistor Automobile Receiver Front End Design—R. Martinengo (p. 31)

This paper discusses the requirements which must be considered in the design of an RF amplifier stage and converter for a transistor automobile receiver. Several coupling networks for the antenna and interstage circuits are discussed and performance data are given for various combinations of circuits. Data are given for a converter circuit including voltage and temperature effects on frequency stability.

A Five-Transistor Automobile Receiver Employing Drift Transistors—R. A. Santilli and C. F. Wheatley (p. 38)

Improvements in Detection, Gain-Control, and Audio-Driver Circuits of Transistorized Broadcast-Band Receivers—D. Thorne and R. V. Fournier (p. 46)

Application of Rotationally Non-Symmetrical Electron Lenses to TV Image Reproduction—D. W. Taylor, N. W. Parker and H. N. Frihart (p. 54)

Recent developments in the art have dictated the division of this paper into two component parts. The first deals with a quadrapolar, magnetic lens of rotational nonsymmetry used to achieve scan magnification with a television cathode ray tube. The second concerns the development of a negative, electrostatic, gauze lens exhibiting full rotational symmetry which is also used to provide scan magnification.

In the discussion, the quadrapole lens is synthesized from component fixed fields and the electron beam trajectories within the lens predicted. An analogy with crossed, positive and negative , cylinder lenses of light optics is expressed. The design of a complete, scan-magnified, image reproducing system is considered.

The theory of the rotationally symmetrical divergent lens is developed from an extension of the theory of bi-potential lenses. Problems of mesh scatter are treated and spot size increase due to mesh scatter is calculated. Other optical problems introduced by the mesh are discussed.

The FM Multiplex Stereo Receiver—H. N. Parker (p. 70)

Circuit Aspects of Parametric Amplifiers—H. Seidel and G. F. Hermann (p. 75)

Parametric amplifiers are distinguished from most active networks in that power is taken directly from an ac source and that the phase of this source is significant in the amplification process. As a consequence of the harmonic spectrum produced by the interaction of the power source (pump) and the nonlinear element, the introduction of a small signal generates a pair of sidebands about each harmonic. Networks with variable parameters may be handled with an extension of the conventional formalism into one of frequency as well as spatial scattering.

We deal with two cases. In the first we consider the lower sideband amplifier which requires only a two frequency dscription; the signal and the lower sideband. Such a system may be optimized by adding equalizing networks whose synthesis stems from passive network procedures.

The second case considers a periodic cascade in which the pump phase is assumed to be varying uniformly. The nature of the natural modes of such a system are derived from general considerations of time and space symmetry. The reactive case is considered specially and orthogonality relations are produced which resemble those of a conventional network chain.

Four Terminal Equivalent Circuits of Parametric Diodes—C. S. Kim (p. 83)

Four terminal equivalent circuits of variable capacitance (parametric) diodes used in various configurations of converters and amplifiers are presented. These equivalent circuits are derived from small signal approximations for the nonlinear dynamic capacitance of a diode. The cases considered involve three frequencies, namely input and output signal frequencies and pumping frequency for converters or input signal frequency, idler and pumping frequencies for amplifiers.

These four terminal equivalent circuits are analogous to those for transistors and vacuum tubes. They help to give an understanding of parametric operation and may be used to obtain expressions for gain, bandwidth and noise figure.

Circuit Theory

Iterative Traveling-Wave Parametric Amplifiers—C. V. Bell and G. Wade (p. 4)

It is well known that the parametric principle can give low-noise amplification at microwave frequencies. The conventional parametric amplifier involves a single variable element and one or more resonant cavities. Such an amplifier is extremely narrow band, it suffers from large changes in gain due to small changes in pump level, and it must be used with a circulator if unilateral gain is desired. These difficulties can be overcome by using a number of variable elements in a traveling-wave circuit.

This paper presents the circuit considerations appropriate to wideband operation in a traveling-wave parametric amplifier. The model which is analyzed is a transmission line periodically loaded with parametric diodes. The diodes constitute the variable elements. Across each diode is fed a large pumping voltage which produces a time-varying capacitance.

A Brillouin diagram for the structure (*i.e.*, a plot of ω vs β) can be computed from the analysis. The conditions for high gain, wide band, and other desirable characteristics are conveniently determined from this diagram.

On the Application of the Base Charge Concepts in the Design of Switching Circuits—R. S. C. Cobbold (p. 12)

This paper described a new method of measuring the effective decay time of excess minority carriers in the base of junction transistors, the results of which show an approximately exponential decay with time. The relation between the decay-time constant and the normal and inverse transistor parameters is discussed, and it is shown how the experimental measurements can be directly applied to the design of transistor pulse circuits.

Using the Ebers and Moll equivalent circuit for a saturated transistor, an analysis is made of the effect on the charge storage caused by the passage of a collector current when the base connection is open circuit. The case of a transient collector current is also examined, and it is concluded that for typical alloy junction transistors the passage of a collector current plays little part in determining the charge storage. Thus, the storage time with open-circuit base is determined by the initial excess charge, the collector current existing when the transistor enters the active region, and the decay time constant for minority carriers. A simple equivalent circuit for determining the decay of stored charge when a reverse base current is applied is also discussed.

Element Coefficients for Symmetrical Two-Section Filters Having Tchebycheff Response in Both Pass and Stop Bands—D. C. Pawsey (p. 19)

Elements coefficient for a normalized symmetrical low-pass filter, having "equal ripple" response in both pass and stop bands, are presented graphically. The coefficients are plotted against the relative selectivity of the filter, with a loss factor as independent parameter. The interval between curves is sufficiently small to permit interpolation with an accuracy of ±1 per cent.

Frequency and impedance transformations are included to allow the elements of a practical filter to be derived from those of the appropriate normalized design.

The loss function corresponding to a particular design is readily formulated in terms of the Loss factor above and the appropriate frequencies of zero loss.

Maximum Gain Realization of an RC Ladder Network—A. Paige and E. S. Kuh (p. 32)

This paper is concerned with the synthesis of the voltage transfer function of an unterminated RC ladder network. Given

$$A(p) = \frac{V_2}{V_1} = K\frac{N(p)}{D(p)},$$

the constraint on N and D is well known and the realization procedure is straightforward. However, for many applications, it is important to realize the maximum possible gain (K max) associated with a given transfer function. This paper presents a method of determining $K_{\max}$ from the given $A(p)$. Furthermore, it is shown that if the maximum gain occurs at dc or at infinite frequency, $K_{\max}$ can be realized exactly. If the maximum gain occurs at a finite frequency, $K_{\max}$ can be approached arbitrarily closely.

On Coefficients of Polynomials in Network Functions—S. L. Hakimi and W. Mayeda (p. 40)

This paper presents a study of the relationships between the missing powers of polynomials in network functions and the network geometry. The elementary transformation of trees and the 2-trees of a network are introduced to obtain the necessary and sufficient conditions for polynomials in network functions to have missing powers. It is shown that the polynomial in the numerator of the transfer function of a grounded two-terminal-pair RLC network cannot have two successive missing powers unless some common factors of the numerator and the denominator are cancelled. This result is useful in topological synthesis where one must usually restore all the necessary surplus factors before deciding on the minimum number of vertices and the geometry of the network.

A General Class of Maximally-Flat Amplitude Response Ladders—Sid Deutsch (p. 45)

It is shown that the elliptical Tchebycheff pole array defines a general class of maximally-flat amplitude functions when the number of poles approaches infinity. The infinite-order pole array can be realized as an infinite cascade of identical two-terminal ladders. The amplitude characteristic of the driving-point impedance of the two-terminal ladder is flat up to the nominal cutoff frequency, ω_0. Beyond ω_0, the exact shape of the amplitude characteristic is determined by the eccentricity of the original pole array. The two-terminal ladder is a low-pass R, L, and C structure that is infinitely long. Two special cases are considered: 1) when the pole array becomes linear, the ladder is a constant-k type; 2) when the pole array becomes circular, the shunt conductances and series resistances of the ladder rapidly taper toward zero while its C and L components taper toward a constant-k type.

Optimum Estimation of Impulse Response in the Presence of Noise—Morris J. Levin (p. 50)

The problem considered is that of estimating the impulse response of a linear system from records of its input and output during a limited interval of time when the system output is obscured by additive random noise. Standard results from statistical estimation theory are applied to derive least squares and Markov estimates which are optimum in the sense of having minimum variance among all linear unbiased estimates. No special assumptions are required concerning the form of the input. Expressions for the variances of the sampling errors are given. The relationships of these estimates to other methods of estimation which have been suggested are discussed.

Demodulated Lead Networks—Erik V. Bohn (p. 56)

One of the possible types of compensating networks for carrier-frequency servo systems is the demodulator lead network. By means of synchronous switching, a nonlinear operation is performed on the envelope of the input. For the case of very high carrier-to-signal-frequency ratio, an equivalent linear circuit is derived which is that of a typical dc lead network. The response to a step input in conjunction with quasistationary Fourier analysis and description of function methods is used to derive the circuit elements. The equivalent circuit is verified experimentally and its range of validity discussed.

Regenerative Modes of Active Networks—E. S. Kuh (p. 62)

An active device with passive imbedding can produce natural frequencies in the right-half plane. In the design of regenerative circuits, it is important to find the permissible location of regenerative modes. In this paper the maximum real part of the natural frequency of an active device under arbitrary passive imbedding is determined. Furthermore, it is shown that this regenerative mode can actually be realized. For the case of a pentode, the required passive network is a gyrator.

Reviews of Current Literature (p. 64)

Correspondence (p. 67)

Electron Devices

Vol. ED-7, No. 1, January, 1960

Tunnel Diodes—R. N. Hall (p. 1)

This paper presents a review of the properties, principles of operation, and implications of the tunnel diode. Following a brief description of the unusual characteristics of this device, a discussion is given of the mechanism which leads to the negative resistance. Experiments showing the transition from the tunnel diode characteristic to that of a high-voltage avalanche diode are exhibited. The electrical characteristics of tunnel diodes are outlined making use of the small-signal equivalent circuit which represents the behavior in the negative resistance region. Diodes designed for high-frequency operation are described and examples are given of circuits which demonstrate their behavior as switches, radio receivers, and microwave oscillators. In connection with a discussion of the temperature dependence of these devices, experiments are described which demonstrate the importance of phonons in determining their characteristics at the temperature of liquid helium.

Prediction of Storage Time in Junction Transistors—R. P. Nanavati (p. 9)

This paper points out that in the prediction of storage time one needs to know only a single fundamental device parameter, the storage time constant T_s. Several methods of measuring T_s are considered and compared both theoretically and experimentally. A single nonoscilloscope method of measuring T_s is discussed and its theory presented. This method holds out the best promise for the ability to predict the storage time of very fast transistors. It is therefore now possible to predict large signal transient response of transistors on the basis of small signal nonoscilloscope measurements.

One-Dimensional Traveling-Wave Tube Analyses and the Effect of Radial Electric Field Variations—J. E. Rowe (p. 16)

The equivalence of the differential-equation and integral-equation approaches to the solution of the nonlinear traveling-wave amplifier problem is shown rigorously. The equations can be transformed one into the other without making any additional assumptions. The space-charge expression developed on the basis of considering the electron distribution in phase space is shown to give the same form for the space-charge weighting function as a space-charge expression based on the electron distribution in space. Efficiency calculations are compared for the two methods and the agreement is excellent. Corrections to earlier calculations are included. The effect of radial electric field variations due to the circuit is considered and it is shown that the efficiency for large streams is reduced in direct proportion to the square of the field reduction function.

Small-Signal Analysis of the Helitron Oscillator—Richard H. Pantell (p. 22)

In this paper, a small-signal analysis of a microwave oscillator, discussed by Watkins and Wada is presented. This tube, the helitron, has an electron beam describing the trajectory of a helix between two concentric cylinders. Interaction is with a TEM mode supported on the inner cylinder, and the beam is focused by having a potential difference between the cylinders. This has been termed an E-type tube.

The E-type tube had originally been conceived as a device for exchanging electron potential energy of an electrostatically focused beam for RF energy. In this manner, one would expect to obtain the high efficiencies associated with an M-type tube, without requiring a magnetic field.

Watkins and Wada presented experimental results in their paper, and they indicated that the theory that had been developed did not predict the observed behavior. In particular, it was stated that if the propagation constants were those of an M-type tube, the measured starting current would be one-fiftieth of the theoretical starting current.

The small-signal analysis of the E-type tube developed in the main body of this paper has yielded two interesting results:

1) The electrons bunch along the direction of rotation, and lose kinetic energy. In this sense the E-type tube behaves similar to the O-type oscillator. Electron motion transverse to the dc path, which is important in the M-type tube, is not important for E-type operation.

2) Space charge forces tend to increase the bunching along the direction of rotation. This results in a negative value for the space-charge parameter, and an attendant reduction in starting current. Growing waves can exist on an electron beam that is electrostatically focused between two conducting cylinders, even without the presence of a circuit field. In this sense the E-type oscillator is similar to the M-type tube.

Generation-Recombination Noise in Semiconductors—The Equivalent Circuit Approach—Keith S. Champlin (p. 29)

Generation-recombination noise in semiconductors in thermal equilibrium is treated from the standpoint of thermal fluctuations in equivalent electrical circuits. For the general volume recombination model, a method based on network reduction is presented which allows one to calculate the spectral density of the electron and hole fluctuations without solving for the spectra of the fluctuations in occupancy of the recombination centers and traps. The method is extended to a surface recombination model, thereby avoiding the ambiguities found in previous formal treatments. It is shown that the concept of ambipolar diffusion, the location and spectral density of the random sources, and the spatial correlation of Fourier coefficients of carrier density fluctuations all have simple significance in electrical terms.

Using transmission line techniques, the generation-recombination (GR) spectrum is calculated for a two-level semiconductor where recombination occurs at opposite plane surfaces. This new result is examined in detail for the limiting cases approached when the recombination process is 1) volume-limited, 2) surface-limited, and 3) diffusion-limited. It is shown that, in the first two cases, the spectrum is identical with that obtained from a zero-dimensional analysis provided the time constant is properly defined. For the diffusion-limited case, however, the spectrum varies as $1/\omega^{3/2}$ at high frequencies, and at low frequencies the noise is 5/6 that predicted by the simple theory. The new result is shown to compare favorably with measurements reported previously by Hill and van Vliet.

Comparison of *N-P-N* Transistors and *N-P-N-P* Devices as Twenty-Ampere Switches—H. W. Henkels and F. S. Stein (p. 39)

A series of 20-ampere silicon *n-p-n* transistors and three-terminal *n-p-n-p* switches have been developed, and their characteristics are compared with respect to high-current switching applications. At the present time, collector-emitter voltages of the transistors are generally lower than those of the switches, which may exceed 400 volts. The *n-p-n* transistors are somewhat simpler to produce than the *n-p-n-p* structures. However, the ultimate current-handling capacity of the latter type of device is greater, because of the uniform current density. The saturation voltage drops at 20 amperes are comparable, being in the order of one to two volts. The switch has a distinct advantage in the turn-on speed, while the transistor has the equally important advantage that the base retains control for turn-off.

Triode Electron Injection Systems for Hollow Beams—L. A. Harris (p. 46)

Novel electron guns, in which a conical hollow electron beam is projected at a large angle to the axis into a coaxial deflection region, were tested. The guns have a triode structure so that the perveance can be varied easily. The strong deflection increases the effective perveance of the beam and makes the trajectories insensitive to current variations. In the form of a device with the gun at a large radius and projecting the beam inward, the electron paths are sensitive to scattering in the gun. The inverted gun, projecting the beam outward, is relatively free from this difficulty. The systems generally behave as expected, and should be quite useful for initiating variable-current hollow electron beams in various available focusing arrangements.

A New Concept in Microwave Gas Switching Elements—Ray S. Braden (p. 54)

A gas switching tube commonly known as a TR tube is an RF energy switch, the operation of which is a function of incident power level. Switch operation is achieved by gaseous ionization. The major problem in the design of gas switching devices has been that of achieving, simultaneously, a short recovery time and a low arc loss. This problem has been eliminated by the development of the device described in this paper. The design objective was to produce a self-contained TR window for operation at very high powers. The arc loss developed by conventional tube design at these high power levels would be sufficient to melt any known window material. The design of this device is such that the ionizable gas blanket takes the form of a thin-walled cylinder suspended in the iris in a dielectric cylinder. This configuration presents a smaller volume of gas with a reduced cross section and a much shorter diffusion length. These changes result in lower leakage power, faster recovery time, and reduced arc loss.

As finally developed, the window does not involve glass-to-metal or ceramic-to-metal seals. The problem of metal sputtering or outgassing is therefore eliminated. By a unique spring pressure support, the problem of strain developed by differences of thermal coefficients of expansion is eliminated. The open-ended design of the cylinder provides excellent facilities for cooling the window.

Prototype units have been successfully operated in *L* band at power levels considerably in excess of 15 mw peak power and 30 kw average power. These units exhibited recovery times of 5 to 20 μsec with high-level attenuation of 26 to 35 db and arc loss below the level of present measuring techniques, *i.e.*, <0.02 db.

A practical window for these high powers with a loaded *Q* of less than 1.5 has been fabricated.

Transistor Behavior at High Frequencies—R. P. Abraham (p. 59)

The tee equivalent circuit for junction transistors has been modified to take account of electric field in the base region. This electric field is the result of a graded impurity density in the base region of the transistor. It is shown that a graded base improves the high-frequency performances of the common base stage; however, the improvement in common emitter performance is considerably less because of the increased "excess" phase which accompanies the improved high-frequency performance. The complex hybrid parameters are calculated for the common base and common emitter configurations; these calculations take into account the parasitic interterminal capacities of the transistor. The common emitter calculations are compared to measure data, and substantial agreement is obtained.

Editorial (p. 1)

A Stochastic Model for Determining the Size and Allocations of the Research Budget—Raoul J. Freeman (p. 2)

An analytical method is presented for determining the size of the research budget and allocating it among competing projects. A stochastic model is utilized. The over-all profit-maximization of the firm is used as a framework. A hypothetical example is given to illustrate the method.

Regression Models for Company Expenditures on and Returns from Research and Development—Ira Horowitz (p. 8)

Data were gathered on the research expenditures, sales, and profits of a sample of large firms which had been conducting organized research for 25 years or more. A linear relationship is hypothesized for explaining the size of the research budget. Several factors influencing the size of the research budget are examined. A regression model is developed for expressing the returns on R & D expenditures with lags up to six years. Suggestions are made for the application and possible uses of the method by an individual firm.

Intracompany Systems Management—Harry H. Goode (p. 14)

Research and Development on complex systems requires experimentation with the organizational form of the technical effort. Three levels of system design are distinguished—the set, the set of sets, and the set of sets of sets. The evolution of complex system design is described. Five organizational modes are examined and evaluated. The crossbar mode is suggested as best for large scale system projects and is described in detail.

Enculturation in Industrial Research—Robert W. Avery (p. 20)

The new researcher undergoes a learning experience in the laboratory, in which he attempts to relate his technical competence to the needs of his employer. More than one hundred members of ten industrial laboratories were interviewed in order to discover the kinds of things the new researcher learns, the problems he encounters, etc., as he first adapts himself to the milieu of the industrial laboratory. Emphasis is placed in the analysis of these data on the factors influencing the kinds of ideas he produces and how he handles ideas.

Some Organizational Factors Affecting Creativity—Norman Kaplan (p. 24)

Until recently, theoretical discussions and careful conceptual analyses have been rare in the literature on creativity. Studies of the organizational and environmental factors affecting the creativity of scientists have also been rare, but are becoming more common. This paper reports on the factors considered important in influencing creativity in a number of research laboratories. The data were gathered through interviews with research directors, administrators, and scientists. Five factors are identified and analyzed.

Role Concept of Engineering Managers—Simon Marcson (p. 30)

This paper contains preliminary results of a questionnaire survey among engineering managers in a large electronics company. Engineering managers are divided into three levels and compared with respect to their degree of business and professional orientation, their conception of authority, and their understanding of the problems of nonsupervisory engineers.

On the Anatomy of Development Projects—Peter V. Norden (p. 34)

The structure of an R & D project is described in terms of an Effort-Distribution Array. A logistic model is presented for the cumulative times series of effort devoted to a project, and problems of using such curves for prediction are discussed. A set of rules is given, which, with the aid of computer simulation, can be used to generate a project schedule. The consequences of several combinations of rules and restrictions are examined.

Human Factors in Electronics

Vol. HFE-1, No. 1, March, 1960

Frontispiece and Editorial—Curtis M. Jansky (p. 2)

Man-Computer Symbiosis—J. C. R. Licklider (p. 4)

Man computer symbiosis is an expected development in cooperative interaction between men and electronic computers. It will involve very close coupling between the human and the electronic members of the partnership. The main aims are 1) to let computers facilitate formulative thinking, as they now facilitate the solution of formulated problems, and 2) to enable men and computers to cooperate in making decisions and controlling complex situations without inflexible dependence on predetermined programs. In the anticipated symbiotic partnership, men will set the goals, formulate the hypotheses, determine the criteria, and perform the evaluations. Computing machines will do the routinizable work that must be done to prepare the way for insights and decisions in technical and scientific thinking. Preliminary analyses indicate that the symbiotic partnership will perform intellectual operations much more effectively than man alone can perform them. Prerequisites for the achievement of the effective, cooperative association include developments in computer time sharing, in memory components, in memory organization, in programming languages, and in input and output equipment.

Pattern Recognition and Display Characteristics—W. R. Bush, V. M. Donahue and R. B. Kelly (p. 11)

This paper reports experimental results of human operator performance in a visual recognition task. The work began with a method of generating families of complex patterns to simulate certain characteristics of visual sensor displays, such as radar and infrared returns. The experimental effort was directed toward establishing criteria for predicting human operator performance in a map-matching task. The operators' task was to recognize which of four patterns presented simultaneously with a reference pattern belonged to the reference pattern family. The measure of performance was the time in seconds taken by the operator to make a selection. Response times were more rapid when the reference pattern was less complex than the comparison than when the reference pattern was the more complex. Analysis of the display characteristics led to the selection of four physical measures to be used in predicting operator performance. These measures—pattern length, pattern density, and two measures of pattern complexity—correlated highly with response time, were not highly intercorrelated, and were applicable to natural sensor returns. The four measures were found to account for a high degree of the total variance. Regression equations were derived which predict performance from known values of the four measures.

The Use of Quickening in One Coordinate of a Two-Dimensional Tracking System—J. W. Duey and R. Chernikoff (p. 21)

In a previous study, it was found that tracking error in one coordinate of a two-dimensional tracking system was affected by the dynamics used in the other coordinate. In particular, tracking performance progressively deteriorated as the dynamics in the two coordinates become more dissimilar. The present study seeks to extend these findings by determining how the introduction of quickening into one coordinate of a second-order, two-coordinate tracking system would affect the performance in the unquickened coordinate. In the light of the previous study, it might be expected that quickening one coordinate would degrade the performance of the other. On the other hand, the simplification of the tracker's task induced by quickening might effect an improvement in performance.

The findings suggest that a counterbalance of the above factors was achieved, since quickening one coordinate had no effect on performance in the other.

Desirable Push-Button Characteristics—Richard L. Deininger (p. 24)

This paper reports the results of studies in a series concerning the characteristics of push-button keysets that people can operate quickly, accurately and conveniently. The studies investigated push-button arrangements, button top and lettering characteristics, and push-button force-displacement characteristics. Considerable latitude exists in the design of keysets if only keying performance is considered. The preference judgments were somewhat more selective, particularly for the force-displacement characteristics of the button mechanism.

The Relation of Electronic and Optical Gain to System Performance—S. Seidenstein and H. P. Birmingham (p. 30)

An experiment was conducted to investigate the effect of adjusting display gain upon man-machine system performance in a simple aided tracking system. Gain was varied in two ways: electrically by changing amplification, and optically by changing the distance from the scope to the eye. Manipulation of gain by each method produced similar changes in system performance. Over the ranges studied, system error decreased as display gain was increased. This result agrees with predictions based upon closed-loop control system theory and suggests the feasibility of including additional experimental variables within the theory.

Theoretical Limitations to Ferromagnetic Parametric Amplifier Performance—R. W. Damon and J. R. Eshbach (p. 4)

It has been commonly expected that improved operation of the ferrite parametric amplifier could be obtained by use of materials of narrower resonance linewidth, ΔH. This parameter is critical in determining the pumping power (P_p) required for operation of the device. Also of importance, however, is the limitation of device properties determined by the dependence on ΔH of the instability threshold of the spin-wave system. Considering this limitation, the maximum voltage gain-fractional bandwidth product ($g_v\Delta\omega/\omega_1$) has been determined as a function of other device parameters, and typical values calculated for several modes of operation. In the electromagnetic mode, for example, there is an optimum ΔH which yields maximum $g_v\Delta\omega/\omega_1$ at a given pumping power. It is also shown that a minimum filling factor, also a function of ΔH for some types of operation, is required to reach the oscillation threshold even in the unloaded device.

An Extension of the Mode Theory to Periodically Distributed Parametric Amplifiers with Losses—K. Kurokawa and J. Hamasaki (p. 10)

For the extension of the mode theory of the lossless periodically distributed parametric amplifier to the lossy case, a "conjugate circuit" is introduced in this paper. The conjugate circuit is an imaginary circuit which is obtained in the passband by replacing each resistance in the original circuit with the negative resistance of the same magnitude. The orthogonality properties between the modes of the original circuit and those of the conjugate circuit are derived. The power gain and the noise figure of the amplifier are calculated, showing the usefulness of this mode theory in accounting for the spreading resistance of the semiconductor diode.

Action of a Progressive Disturbance on a Guided Electromagnetic Wave—J. C. Simon (p. 18)

Periodic and Guiding Structures at Microwave Frequencies—A. F. Harvey (p. 30)

The paper reviews the properties of periodic and guiding structures which now play an important part in the operation of components, antennas, electron tubes and low-noise amplifiers. An account is first given of dispersive propagation in periodic-loaded lines, showing how the frequency characteristic breaks into pass and stop bands. The formation of forward- and backward-space harmonics and the effects of systematic modification of loading are examined. A description is then given of the various types of surface-wave structures including dielectric rods, dielectric-clad metals, and corrugated surfaces, as well as surface wave instruments and circuits. Practical slow-wave structures such as ladder lines, coupled cavities and helices are finally treated. The survey concludes with a bibliography.

Design of Mode Transducers—L. Solymar and C. C. Eaglesfield (p. 61)

The propagation of the electromagnetic wave in a gradual transducer is discussed. It is shown that the incident mode and the geometry of the transducer determine the outgoing mode. Inverting this theorem, a method is suggested for the design of the transducer's surface for cases in which the desired modes in the uniform waveguides are given.

The application of the method is illustrated in three examples.

UHF Resonator with Linear Tuning—B. H. Wadia and R. L. Sarda (p. 66)

A novel method of tuning a transmission-line type resonator is described. The first-order theory of such a resonator is derived and presented in the form of design curves which indicate an extremely good tuning linearity. Experiments with a resonator designed on this principle agree with theory.

Equivalent Circuits for Small Symmetrical Longitudinal Apertures and Obstacles—Arthur A. Oliner (p. 72)

Formulas based on small aperture and small obstacle theory are presented for the determination of equivalent circuits for symmetrical longitudinal apertures and obstacles. These formulas are then applied to several examples of practical interest, including aperture discontinuities in trough waveguide and an obstacle array of interest to anisotropic radomes.

On the TE$_{n0}$ Modes of a Ferrite Slab Loaded Rectangular Waveguide and the Associated Thermodynamic Paradox—A. D. Bresler (p. 81)

It has been known for some time that the secular equation for the TE$_{n0}$ modes of a perfectly conducting rectangular waveguide loaded with a transversely magnetized dissipationless full height ferrite slab located against one of the narrow walls of the waveguide admits the possibility of the existence of only a single propagating mode (transporting energy in one direction only). In this paper, it is established that if we admit the existence of a passive dissipationless uniform waveguide supporting only a single propagating mode we are led inescapably to a thermodynamic paradox. A uniqueness theorem is cited to establish that, for the waveguide described above, the paradox is associated with the TE$_{n0}$ mode set alone. This conclusion motivates a thorough study of the secular equation for the TE$_{n0}$ modes of this waveguide. This study is initiated by an investigation into the properties of the TE$_{n0}$ surface waves guided along a plane interface separating a transversely magnetized dissipationless ferrite from free space. It is shown that two oppositely directed surface waves are guided along this interface. These two surface waves are admitted in different finite ranges of the parameter values which never coincide and which may or may not overlap. Each of the two surface waves has both a high- and a low-frequency cutoff and, in general, both a high and a low dc magnetic field cutoff. The propagation constant of one of the surface waves becomes infinite at the low field (high-frequency) cutoff. The next step in the analysis consists of an examination of the behavior of these surface waves on finite thickness ferrite slabs located in different environments. It is shown that when one of the two interfaces bounding the slab approaches a short circuit the infinite propagation constant noted above behaves in a peculiar discontinuous fashion. Next, the TE$_{n0}$ mode secular equation of the slab loaded rectangular waveguide is analyzed and information is developed leading to a description of the behavior of the propagation constants of all the propagating TE$_{n0}$ modes. This analysis reveals that the possibility of the existence of only a single propagating mode is associated only with the surface wave mode of this waveguide. A resolution for the thermodynamic paradox is proposed based on the discontinuous behavior of one of the infinite propagation constants associated with this surface wave mode. It is shown that with a properly chosen secular equation for the waveguide under consideration there are always an even number of TE$_{n0}$ propagating modes, half of which transport energy in one direction, half in the other. This demonstration is based, in part, on an analysis leading to relations between the direction of the power flow associated with a propagating mode and the derivative of its propagation constant with respect to the dc magnetic field.

***L*-Band Ferromagnetic Resonance Experiments at High Peak Power Levels**—E. Schlomann, J. Saunders, and M. Sirvetz (p. 96)

Ferromagnetic resonance absorption at high peak power levels has been observed at 1300 mc in yttrium-gadolinium garnets and in a nickel ferrite-aluminate. In agreement with theoretical predictions, the critical field characterizing the onset of nonlinear effects, in a series of yttrium-gadolinium garnet disks of a given shape, was found to be very sensitively dependent on the gadolinium content. Similarly, for samples of a given composition, the critical field strength was sensitively dependent on the shape of the sample in agreement with theoretical predictions. At moderate power levels the susceptibility varies linearly with the square of the RF magnetic field strength over an appreciable range. This result can be understood in terms of an extension of Suhl's theory. The results can be used to predict the high power performance of these materials when used in isolators.

High Power Ferromagnetic Resonance at *X*-Band in Polycrystalline Garnets and Ferrites—J. J. Green and E. Schlomann (p. 100)

Resonance experiments have been performed at *X*-band on spherical samples of polycrystalline yttrium garnet, yttrium-gadolinium garnet, yttrium-holmium garnet and nickel-cobalt ferrite. The RF field strength extended up to 60 Oersted. In the case of yttrium garnet the samples differed considerably in density and hence in linewidth. At fairly low power levels the susceptibility at resonance varies linearly with the square of the RF magnetic field strength. At high power levels the susceptibility is inversely proportional to the amplitude of the microwave magnetic field. The "spin-wave linewidth" ΔH_k is inferred by extrapolation from the behavior at very high powers. It is found that ΔH_k is, to a large extent, independent of the linewidth ΔH observed by the usual low power experiments. In particular ΔH_k was found to be essentially the same (approximately 4 Oe) for all yttrium iron garnets (single crystals and polycrystals with linewidth varying between 1.8 Oe and 450 Oe). On the other hand, ΔH_k increases very rapidly if the yttrium is partially substituted by holmium ($\Delta H_k \sim 11$ Oe for 1 per cent substitution).

Microwave Diode Cartridge Impedance—R. V. Garver and J. A. Rosado (p. 104)

In any application of a semiconductor microwave diode, the impedance of the diode cartridge plays a very important role. Two commonly made assumptions, which are quite erroneous, are that 1) the impedance of the diode cartridge consists simply of a shunt capacitance and whisker inductance, and 2) the metal-to-semiconductor junction at microwave frequencies behaves approximately as it does at 10 mc. In this paper it is shown that the impedance of the diode cartridge at microwave frequencies can be measured accurately by substituting a carbon die for the semiconductor.

Theory of the Germanium Diode Microwave Switch—R. V. Garver, J. A. Rosado and E. F. Turner (p. 108)

The application of a generally neglected theory of microwave detection to the poorly understood problem of metal-to-semiconductor junction behavior at microwave frequencies is discussed. Experimental results are disclosed which support the theory and appear to be the first experimental verification of it. It is shown how the theory predicts that germanium microwave diodes should exercise direct switching action upon microwaves while silicon microwave diodes should not, as had been observed in the past but with no explanation.

Improvement in the Square Law Operation of 1N23B Crystals From 2 to 11 KMC—A. Staniforth and J. H. Craven (p. 111)

Crystal rectifiers have been used for many years as video detectors in microwave measurements. In most of the applications the detection characteristic at low level is assumed to be square law. It is well known that, in general, this assumption is not justified, particularly if reasonable accuracy is desired. The conditions required to increase the dynamic range over which square law response may be achieved have been investigated experimentally. Results obtained in this laboratory have indicated that a forward bias current of 100 microamperes or more with a low video load resistance made the operation of the crystal closer to the ideal square law over a larger dynamic range.

An *N*-Way Hybrid Power Divider—Ernest J. Wilkenson (p. 116)

A circularly symmetric power divider is described which splits a signal into *n* equiphase equiamplitude parts where *n* can be odd or even. The power divider provides isolation between output terminals and approximately matched terminal impedances over about a 20 per cent band. A theory of operation is given which yields the necessary design parameters, and an experimental model is described which has a minimum isolation of -27 db between output terminals, an output VSWR of 1.6, and an input VSWR of 1.2.

UDC NUMBERS

Certain changes and extensions in UDC numbers, as published in PE Notes up to and including PE 666, will be introduced in this and subsequent issues. The main changes are:

Artificial satellites:	551.507.362.2	(PE 657)
Semiconductor devices:	621.382	(PE 657)
Velocity-control tubes, klystrons, etc.:	621.385.6	(PE 634)
Quality of received signal, propagation conditions, etc.:	621.391.8	(PE 651)
Color television:	621.397.132	(PE 650)

The "Extensions and Corrections to the UDC," Ser. 3, No. 6, August, 1959, contains details of PE Notes 598–658. This and other UDC publications, including individual PE Notes, are obtainable from The International Federation for Documentation. Willem Witsenplein 6, The Hague, Netherlands, or from The British Standards Institution, 2 Park Street, London, W.1., England.

ACOUSTICS AND AUDIO FREQUENCIES

534.2 **1084**
On Waveguide Sound Propagation in Layered Inhomogeneous Media—E. P. Masterov. (*Akust. Z.*, vol. 5, no. 3, pp. 332–336; 1959.) Experimental investigation of sound propagation in a medium in which the square of the refractive index varies according to an exponential law.

A list of organizations which have available English translations of Russian journals in the electronics and allied fields appears at the end of the Abstracts and References section.

The Index to the Abstracts and References published in the PROC. IRE from February, 1959 through January, 1960 is published by the PROC. IRE, June, 1960, Part II. It is also published by *Electronic Technology* (incorporating *Wireless Engineer* and *Electronic and Radio Engineer*) and included in the April, 1960 issue of that Journal. Included with the Index is a selected list of journals scanned for abstracting with publishers' addresses.

534.2–13 **1085**
On the Diffusion of Sound Waves in a Turbulent Atmosphere—R. H. Lyon. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 1176–1182; September, 1959.) The directional and frequency diffusion of a plane monochromatic sound wave in statistically homogeneous, isotropic, and stationary turbulence is analyzed theoretically.

534.2–14:534.88 **1086**
Model Experiments on Sound Propagation in Shallow Seas—A. B. Wood. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 1213–1235; September, 1959.) Detailed report of an experimental study including a description of a scanning technique which gives a complete picture of a low-intensity sound field in a vertical plane in the water.

534.213–8 **1087**
Measurement of Velocity and Attenuation of Ultrasonic Surface Waves in Solid Materials—K. N. Vinogradov and G. K. Ul'yanov. (*Akust. Z.*, vol. 5, no. 3, pp. 290–293; 1959.) Report of measurements made on metals, alloys and glass by a standing-wave method using a proximity magneto-acoustic converter. Damping was measured by a pulse method. Oxidation of an alloy sample increased the surface-wave attenuation at 8 mc from 0.08 to 0.25 db/cm.

534.213.4 **1088**
Characteristic Parameters of Propagation in Lined Ducts—R. S. Piazza. (*Acustica*, vol. 9, no. 3, pp. 129–134; 1959.)

534.213.4 **1089**
Three-Dimensional Investigation of the Propagation of Waves in Hollow Circular Cylinders: Parts 1 and 2—D. C. Gazis. (*J. Acoust. Soc. Amer.*, vol. 31, no. 5, pp. 568–578; May, 1959.) The frequency equation for the propagation of free harmonic waves along a cylinder of infinite extent is derived and evaluated for some representative cylinders.

534.232–8:537.228.1 **1090**
On the Spatial Resolving Power of Barium Titanate and Quartz Plates for Ultrasonic-Field Imaging—K. Hartwig. (*Acustica*, vol. 9, no. 2, pp. 109–117; 1959. In German.) Acoustic measurements of the amplitude distribution of forced vibrations of different-sized plates in the range 3.9–9.5 mc and with excitation restricted to a narrow region of the plate, are considered in relation to electrical measurements of their natural vibrations. Optimum thickness and frequency limits for piezoelectric plates in ultrasonic image converters [see *e.g.* 2084 of 1959 (Freitag and Martin)] are discussed.

534.26 **1091**
Diffraction of a Convergent Cylindrical Wave by a Sphere—I. N. Kanevskiĭ. (*Akust. Z.*, vol. 5, no. 3, pp. 294–300; 1959.) An expression is derived for the resulting field potential and asymptotic expressions are obtained for the intensity of the scattered wave and the effective scattering cross section.

534.283:546.621 **1092**
Acoustic Attenuation in Aluminium due to Electron-Lattice Interaction—E. Lax. (*Phys. Rev.*, vol. 115, pp. 1591–1594; September 15, 1959.) Measured attenuation was proportional to the electrical conductivity and increased with the square of the frequency, but was 50 per cent greater then could be explained by existing theory.

534.283–8:546.815:538.6 **1093**
The Effect of the Direction of a Transverse Magnetic Field on the Electronic Component of Ultrasonic Absorption in a Lead Single Crystal—L. Mackinnon, A. Myers, and M. T. Taylor. [*Proc. Phys. Soc.* (*London*), vol. 75, pp. 773–775; December 1, 1959.]

534.286–14 **1094**
Compressional Relaxation in Liquids—R. E. Nettleton. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 557–567; May, 1959.)

534.286.2 **1095**
The Oscillation of Air Particles in Porous Sound-Absorber Models—H. W. Helberg. (*Acustica*, vol. 9, no. 3, pp. 155–163; 1959. In German.) Entry impedance is calculated for a given Rayleigh-type model and the damping and phase velocity in front of the absorber are determined for grazing incidence. Measurements on three models placed on the walls of a rectangular tube are described.

534.286.2 **1096**
Absorption of Sound by a Strip of Absorptive Material in a Diffuse Sound Field—T. D. Northwood, M, T. Grisaru, and M. A. Medcof. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 595–599; May, 1959.) The method of Levitas and Lax (2314 of 1951) is extended to determine random-incidence absorption.

534.62 **1097**
The New Anechoic Room of the Centre National d'Ètudes des Télécommunications—P. Chavasse and R. Lehmann. (*Ann. Télécommun.*, vol. 14, pp. 72–83; March/April,

1959.) The construction of the room is described in detail and its acoustic characteristics are given.

534.75 1098

Binaural Listening and Interaural Noise Cross-Correlation—I. Pollack and W. J. Trittipoe. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 1250–1252; September, 1959.) The identification of different interaural correlations is examined over a wide range of reference correlations.

534.76:621.395.623.7 1099

Listener Reaction to Stereophonic Reproduction by Reflected Sound—S. E. Levy, G. W. Sioles, V. Brociner, and R. W. Carlisle. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 1256–1259; September, 1959.) Data are presented on the evaluation of various loudspeaker arrangements making use of reflections from the walls of the room in which the stereophonic sound field is produced.

534.79 1100

Curves of Equal Loudness for Octave-Filtered Noise in a Diffuse Sound Field—L. Cremer, G. Plenge, and D. Schwarzl. (*Acustica*, vol. 9, no. 2, pp. 65–75; 1959. In German.) Measurement equipment and its mode of operation are described. A noise-level meter based on data for a diffuse sound field showing a fall of about 3 db per octave is considered.

534.79 1101

On the Lambda Loudness Function, Masking, and the Loudness of Multicomponent Tones—W. R. Garner. (*J. Accoust. Soc. Amer.*, vol. 31, pp. 602–607; May, 1959.) A computational procedure is presented for determining the loudness of multicomponent tones. See 1062 of 1959.

534.833:534.286.2 1102

Three-Dimensional Multiresonant Sound Absorber—M. Abramchik and I. Maletskiĭ. (*Akust. Z.*, vol. 5, no. 3, pp. 275–281; 1959.) Description of a small absorber with perforated flexible walls of transparent material which can be hung from the ceiling. An experimental investigation of the optimum height and spacing of absorbers for noise reduction is reported.

621.395.623.7.001.4 1103

Measurements on Loudspeakers in their Places of Use—T. S. Korn and J. Hougardy. (*Acustica*, vol. 9, no. 3, pp. 121–126; 1959. In French.) Response curves of different loudspeaker units measured a) in an echo-free chamber and b) in listening rooms are compared. The lack of correlation between the two sets of curves is underlined. "Room amplification" is defined and a standard-listening-room procedure is suggested for practical measurements.

621.395.625.3 1104

The Recording Process in Magnetic Sound Recording in Preisach's Representation—G. Schwantke. (*Frequenz*, vol. 12, pp. 383–394; December, 1958.) The analysis of magnetization processes on the basis of Barkhausen-jump statistics using the Preisach diagram is developed. The study of the recording mechanism by this method provides a satisfactory explanation of certain observed effects (see 375 of February), and may give a quantitative interpretation of the recording process.

681.844.08 1105

Analysis of a Piezoelectric Phonograph Transducer as a Function of the Clamping Position—D. H. Howling. (*J. Acoust. Soc. Amer.*, vol. 31, pp. 620–627; May, 1959.) Recording and play-back response characteristics of a laterally vibrating transducer are investigated using a transmission-line analog.

ANTENNAS AND TRANSMISSION LINES

621.372.8:537.226 1106

An Image-Line Coupler—D. J. Angelakos. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 391–392; July, 1959.) A study of the coupling due to a hole made through the image plane. Results obtained with an experimental coupler at 24.4 kmc and a note on its application as a directional coupler are given.

621.372.823:621.372.852.22 1107

Propagation Constants of Circular Cylindrical Waveguides Containing Ferrites—H. K. F. Severin. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 337–346; July, 1959. Abstract, Proc. IRE, vol. 47, p. 1796; October, 1959.)

621.372.826 1108

O-Guide and X-Guide: an Advanced Surface-Wave Transmission Concept—M. Sugi and T. Nakahara. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 366–369; July, 1959. Abstract, Proc. IRE, vol. 47, p. 1796; October, 1959.)

621.372.829 1109

The Transmission of TE_{01} Wave in Helix Waveguides—T. Hosono and S. Kohno. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 370–378; July, 1959. Abstract, Proc. IRE, vol. 47, p. 1796; October, 1959.)

621.372.831 1110

Design of Linear Double Tapers in Rectangular Waveguides—R. C. Johnson. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 374–378; July, 1959. Abstract, Proc. IRE, vol. 47, p. 1796; October, 1959.)

621.372.831 1111

Spurious Mode Generation in Nonuniform Waveguide—L. Solymar. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 379–383; July, 1959. Abstract, Proc. IRE, vol. 47, p. 1796; October, 1959.)

621.372.831.2 1112

Waveguide Bend—D. Wray and R. A. Hastie. (*Electronic Tech.*, vol. 37, pp. 76–83; February, 1960.) A design procedure is given for a sharp bend of continuously changing radius of curvature. Results obtained with an experimental bend compare favorably with those for a "slow" bend of considerably greater size.

621.372.832.6 1113

A High-Power Diplexing Filter—L. Young and J. Q. Owen. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 384–387; July, 1959. Abstract, Proc. IRE, vol. 47, pp. 1796–1797; October, 1959.)

621.372.832.8 1114

New Microwave Circulators—H. N. Chait and T. R. Curry. (*Electronics*, vol. 32, pp. 81–83; December 18, 1959.) The operation of the Y-circulator is explained, and different methods of introducing the ferrite are discussed. Experimental results are given, and advantages and applications of the circuit are described.

621.372.832.8 1115

Circulators at 70 and 140 kMc/s—J. B. Thaxter and G. S. Heller. (Proc. IRE, vol. 48, pp. 110–111; January, 1960.) The design of H-plane Y-junctions and their insertion loss and isolation characteristics are given.

621.372.832.8 1116

A Strip-Line L-Band Compact Circulator—L. Davis, Jr., U. Milano, and J. Saunders. (Proc. IRE, vol. 48, pp. 115–116; January, 1960.) Isolation, insertion loss and VSWR characteristics are given for a symmetrical Y-type junction.

621.372.837.3 1117

A Ferrite Cutoff Switch—R. F. Soohoo. (Trans. IRE on Microwave Theory and Techniques, vol. MTT-7, pp. 332–336; July, 1959. Abstract, Proc. IRE, vol. 47, p. 1796; October, 1959.) See also 1974 of 1958.

621.396.674.3 1118

The Driving-Point Impedance of Cylindrical Antennas Conically Tapering at the Base—R. Kümmich. (*Frequenz*, vol. 12, pp. 369–379; December, 1958.) Results are given of impedance measurements on microwave antennas which are conically tapered at the junction with the coaxial feeder. Locus curves of input impedance as a function of diameter/length ratio d/l are plotted for tapers of 45 degrees, 60 degrees and 90 degrees. Curves of resistance as a function of d/l for current and voltage resonances are derived, and comparisons are made with the results obtained by other authors.

621.396.674.3 1119

The Performance of a Balanced Aerial when Connected Directly to a Coaxial Cable—G. D. Monteath and P. Knight. (*Proc. IEE*, Part B, vol. 107, pp. 21–25; January, 1960.) Various configurations are discussed. Measured vertical and horizontal polar diagrams are given for dipoles and Yagi arrays having their elements vertical, and with the driven element connected directly to the coaxial down-lead. The vertical radiation patterns are appreciably distorted (less for arrays than for a dipole), and the sensitivity to interference from sources near to and below the antenna is increased.

621.396.676:629.19 1120

Aerials in Space—M. G. Chatelain. (*Onde élect.*, vol. 39, pp. 785–788; October, 1959.) Problems associated with communication in space are examined and the spherical equiangular spiral is proposed as a suitable antenna, having the required characteristics of large bandwidth and variable polarization.

621.396.677.3 1121

Pattern Synthesis—Simplified Methods of Array Design to Obtain a Desired Directive Pattern—G. H. Brown. (*RCA Rev*, vol. 20, pp. 398–412; September, 1959.) Mathematical methods of determining the magnitude and phase of the current distribution over an extended linear antenna aperture are described. The radiation pattern and current distribution form a set of Fourier transforms.

621.396.677.83 1122

The Backfire Antenna, a New Type of Directional Line Source—H. W. Ehrenspeck. (Proc. IRE, vol. 48, pp. 109–110; January, 1960.) A Yagi antenna is directed at a plane reflector so that the surface wave traverses the elements a second time. Experimental results show that increases in gain greater than 3 db can be obtained.

AUTOMATIC COMPUTERS

681.142 1123

Computers and Computer Equipment Design—(*Electronic Equip. Engrg.*, vol. 7, pp. 63–98; October, 1959.) A group of nine papers on practical aspects of digital-computer design and recently developed techniques.

681.142 1124

Electronic Computers and the Electronic Computer Study Centre at Pisa—M. Conversi (*Nuovo Cim.*, vol. 11, Supplement no. 3, pp. 376–396; 1959.) Outline of the program and future development of the Center with detail of available equipment. See also 3966 of 1959 (Caracciolo and Guerri).

681.142 1125

Solid-State Digital Code-to-Code Converter—R. Wasserman and W. Nutting. (*Electronics*, vol. 32, pp. 60–63; December 11, 1959.) 13 bits of Gray code can be changed to normal binary code by means of the converter described. The basic building block is a circuit comprising a magnetic core, a junction transistor, and a delay network. Thyratrons are used for the read-out display.

681.142 1126

A High-Speed Ferrite Storage System—C. J. Quartly. (*Electronic Engrg.*, vol. 31, pp. 756–758; December, 1959.) A read/write cycle time of 0.5 μsec can be achieved in the small store described.

681.142 1127

The Magnetic Drum Store of the "Mercury" Computer—K. I. Turner and J. E. Thompson. (*Electronic Engrg.*, vol. 32, pp. 16–21; January, 1960.) Explanatory circuit diagrams, mechanical drawings, and performance data of the Type-1909 drum are given.

681.142 1128

Approximation Errors in Diode Function Generators—N. Ream. (*J. Electronics Control*, vol. 7, pp. 83–96; July, 1959.) Errors resulting from fitting a piecewise-linear function to a smooth curve are discussed in relation to analog-computer applications. A simple integral based on best-fit criteria will give the relation between number of segments and error and also the break points between segments. Numerical results are given for typical functions.

681.142:621.374.3 1129

Theoretical Study and Method of Operation of a Logarithmic Integrator—R. G. Nicolo. (*Onde élect.*, vol. 39, pp. 816–822; October, 1959.) Description of a computer circuit based on a diode-pump action.

681.142:621.382.3 1130

The Construction of a Digital Computing System from a Basic Transistor Circuit—P. L. Cloot and G. E. Jackson. (*Electronic Engrg.*, vol. 32, pp. 37–43; January, 1960.) The computer uses 335 identical basic circuits to convert decimal numbers to and from the binary scale. Diagrams of the basic circuit and the system are given. Printed circuits are used.

681.142:621.383.4 1131

Light-Pen links Computer to Operator—B. M. Gurley and C. E. Woodward. (*Electronics*, vol. 32, pp. 85–87; November 20, 1959.) Using a photodiode to read dots produced on a cr tube enables an operator to control an associated computer. By pointing the light-pen at certain dots, information can be written in to the computer.

681.142:621.391.812.8 1132

Computers aid Propagation Studies—(*See* 1375.)

681.142:621.397.3 1133

Automatic Character Recognition—D. A. Young. (*Electronic Engrg.*, vol. 32, pp. 2–10; January, 1960.) Limitations and future developments of existing machines are discussed. Further analysis of the semantic features of character patterns and of their recognition limits leads to a "semantic pattern definition" which is sufficiently general to permit recognition of nearly illegible characters.

681.142:697.9 1134

How Analogue Networks Solve Air-Conditioning Problems—W. L. Wright and C. A. Booker. (*Electronics*, vol. 32, pp. 34–37; December 25, 1959.) The thermal properties of a unit area of the structural elements are represented by an equivalent electrical circuit. A complete block diagram shows how these are used to simulate the thermal behavior of a room and its air conditioning system. Some detailed circuitry is given.

CIRCUITS AND CIRCUIT ELEMENTS

621.3.049.7 1135

Three Approaches to Microminiaturization—R. Langford. (*Electronics*, vol. 32, pp. 49–52; December 11, 1959.) Construction methods for extremely small electronic circuits are detailed.

621.3.049.7 1136

British Approaches to Microminiaturization—G. W. A. Dummer. (*Electronics*, vol. 33, pp. 71–75; January 1, 1960.) See 409 of February.

621.318.4.042.1:621.397.62 1137

The Properties of Ferrite U-Cores for Horizontal-Deflection Output Transformers—R. Fälker and E. E. Hücking. (*Elektron. Rundschau*, vol. 13, pp. 3–9; January, 1959.) The results of measurements made with a special core tester (3057 of 1959) are given and discussed.

621.318.57 1138

Steering Circuits control Reversible Counters—R. D. Carlson. (*Electronics*, vol. 33, pp. 86–88; January 1, 1960.) A four-stage bistable multivibrator system is used to provide decade counting. Complementary outputs from each stage are switched to succeeding stages to give either addition or subtraction.

621.318.57:621.382.3 1139

Approximate Calculation of Bistable Switching Circuits using Junction Transistors. Case of Switching Circuits with Common Emitter Resistance—C. Mira. (*Compt. rend.* vol. 249, pp. 384–386; July 20, 1959.) Application of the method described earlier for the case of double-bias operation (53 of January).

621.319:537.226/.228.1 1140

Dielectric Devices—G. T. Wright. (*Nature*, vol. 185, pp. 360–361; February 6, 1960.) Report of a conference held in the Electrical Engineering Department of the University of Birmingham, September 14–17, 1959.

621.372:517.942 1141

On Stochastic Linear Systems—J. C. Samuels and A. C. Eringen. (*J. Math. Phys.*, vol. 38, pp. 83–103; July, 1959.) Systems governed by *n*th-order linear differential equations having random coefficients are studied and the methods developed are applied to a RLC circuit having random capacitance variations.

621.372.413 1142

Design of Open-Ended Microwave Resonant Cavities—D. C. Thorn and A. W. Straiton. (TRANS. IRE ON MICROWAVE THEORY AND TECHNIQUES, vol. MTT-7, pp. 389–390; July, 1959.) Two types of cavity for refractive-index measurements are described, one rectangular in cross section, the other cylindrical. The cavities are terminated in short sections partitioned so that each subdivision is a waveguide operating below the cut-off frequency of the cavity.

621.372.413:678.5 1143

Plastic Microwave Cavities for EPR—P. F. Chester, P. E. Wagner, J. G. Castle, Jr., and G. Conn. (*Rev. Sci. Instr.*, vol. 30, pp. 1127–1128; December, 1959.) An X-band TE_{102} plastic cavity for studies of relaxation in electron paramagnetic resonance is described. It has a Q of 4000 at room temperature and 6000 at 4.2°K.

621.372.44 1144

Generalization to Nonlinear Networks of a Theorem due to Heaviside—S. Duinker. (*Philips Res. Rep.*, vol. 14, pp. 421–426; October, 1959.) A theorem, enunciated by Heaviside and proved by Lorentz for linear electromagnetic systems subjected to a suddenly impressed constant electric force, is extended to electrical networks comprising nonlinear reactances and linear resistance.

621.372.5 1145

Classes of 4-Pole Networks having Nonlinear Transfer Characteristics but Linear Iterative Impedances—E. C. Cherry. (PROC. IRE, Part B, vol. 107, pp. 26–30; January, 1960.) A graphical representation is introduced which simplifies the analysis of networks containing nonlinear elements. The properties of "dual" nonlinear resistances, in which the I/V relation for one resistance is the same as the V/I relation for the other are considered. Such "duals," if realizable, would permit the design of nonlinear four-poles having linear iterative impedances, which could be cascaded.

621.372.5:621.391.822 1146

Theory of Noisy Two-Port Networks—E. F. Bolinder. (*J. Franklin Inst.*, vol. 267, pp. 1–23; January, 1959.) The geometric-analytic theory presented is based on the isometric-sphere method (see 17 of 1958) and on a three-dimensional conformal transformation. 50 references.

621.372.51 1147

Impedance Transformations through Lossless Two-Ports Represented by Fractional Linear Transformations of the Unit Circle—K. Jost. (*Philips Res. Rep.*, vol. 14, pp. 301–326; August, 1959.) The automorphism of a unit circle corresponding to an impedance transformation is characterized by three parameters and can be represented by three successive elementary transformations. This leads to a simple graphical method using Carter or Smith charts for the determination of the transformed impedance and for the treatment of cascades of lossless two-ports.

621.372.54 1148

Constant-Resistance All-Pass Networks with Maximally Flat Time Delay—L. Weinberg. (*J. Franklin Inst.*, vol. 267, pp. 35–53; January, 1959.) Practical design tables are given and their use is illustrated by examples.

621.372.54 1149

The Loss Attenuation in the Pass Band of Wave Filters with Differing Coil Q-Factors—J. Böhse. (*Frequenz*, vol. 12, pp. 380–383; December, 1958.) The loss contributions of the individual coils are summed using weighting functions. Application of the method to a crystal-filter half-section is explained.

621.372.544:621.374.5 1150

An Analysis of a Type of Comb Filter—A. G. J. MacFarlane. (*Proc. IEE*, Part B, vol. 107, pp. 39–52; January, 1960.) A theoretical analysis and discussion of practical devices for use in radar as moving-target indicators and signal integrators. 28 references.

621.372.6:621.391 1151

Calculation of the Static Characteristic of a Nonlinear Multipole without Inertia when the Dynamic Characteristic is Known—G. Papadopoulov. (*Ann. Télécommun.*, vol. 14, pp. 43–48; January/February, 1959.)

621.372.63:621.372.54 1152

High-Frequency Transistor Filter Synthesis—L. M. Vallese. (*Electronic Engrg.*, vol. 31, pp. 748–752; December, 1959.) Two canonical ladder structures of hybrid-Π and hybrid-T type are considered. The intrinsic feedback factor is ignored. Examples of cascaded structures are given.

621.373.4 1153

The Effect of Cathode Impedance on the Frequency Stability of Linear Oscillators—C. T. Kohn. (PROC. IRE, vol. 48, pp. 80–88; January, 1960.) Long-term frequency instability, due to the growth of an interface layer between oxide coating and cathode, may be reduced by suitably adjusting the ratio of anode-to-grid RF voltages.

621.373.4:621.396.62 1154

Voltage Sensitivity of Local Oscillators—W. Y. Pan. (*RCA Rev.*, vol. 20, pp. 473–484; September, 1959.) The dependence of the oscillation frequency of tube oscillators on certain operating conditions is discussed and defined mathematically in terms of independent variables.

621.373.44 1155

How to Generate Accurate Sawtooth and Pulse Waves—C. A. Von Urff and R. W. Ahrons. (*Electronics*, vol. 32, pp. 64–66; December 11, 1959.) Two circuits giving stable sawtooth and rectangular pulse outputs are described, in which a high-speed switching transistor is controlled by a Zener diode. Pulse width and amplitude and waveform timing are independent of active elements in the circuit.

621.374.4 1156

A Method of Combining Two Frequencies—L. R. Kahn. (PROC. IRE, vol. 48, pp. 118–119; January, 1960.) A new method of frequency synthesis is described in which two equal-amplitude tones are combined by limiting, phase inverting and selecting the correct polarity at a control gate.

621.375.012 1157

The Definition of Noise Factor when Applied to Systems containing Negative-Resistance Elements—B. L. Humphreys. (*J. Electronics Control*, vol. 7, pp. 77–81; July, 1959.) The concept of available power and the definition of noise factor are extended to include negative resistance by using the idea of exchangeable power. See 2387 of 1957 (Haus and Adler).

621.375.227 1158

Wide-Band Analysis of Valve Phase-Splitting Circuits—L. J. Giacoletto. (*Electronic Engrg.*, vol. 31, pp. 733–735; December, 1959.) Accurate and approximate design data are developed and compared with results of measurements. Near-ideal operating conditions can be obtained up to a few megacycles with suitable load impedances.

621.375.4 1159

Analysis of the Transistor Cascode Configuration—J. R. James. (*Electronic Engrg.*, vol. 32, pp. 44–48; January, 1960.) Neutralization is not necessary; more gain per unit volume and weight is achieved than in other transistor configurations, while cost per unit gain is about equal to that of more conventional circuits.

621.375.4:621.395.665.1 1160

Transistor Constant-Volume Amplifier—G. J. Pope. (*Wireless World*, vol. 66, pp. 88–91; February, 1960.) Design and circuit details of a microphone amplifier providing substantially similar output signal levels for various speech input levels.

621.375.4.029.33:621.397.6 1161

Transistors in Video Equipment—P. B. Helsdon. (*J. Brit. IRE*, vol. 19, pp. 753–767; December, 1959. Discussion, p. 768.) The importance of the product current-gain × bandwidth is discussed. A new design method is described which gives greater gain-bandwidth factors. The conditions for maximum signal-to-noise ratio are determined and confirmed experimentally. Signal-to-noise ratios and gain-bandwidth factors are comparable to those of tubes.

621.375.4.121.2 1162

Transistorized Distributed Amplifier—C. W. McMullen. (*Rev. Sci. Instr.*, vol. 30, pp. 1109–1113; December, 1959.) The characteristic impedance of both the base and collector transmission lines is 43.4 Ω. A four-section amplifier stage has a gain of about 5 db from 10 cps to 200 mc.

621.375.9:538.569.4 1163

Solid-State Maser Amplifier—S. A. Ahern. (*Electronic Tech.*, vol. 37, pp. 59–63; February, 1960.) The principles of maser operation are introduced and the essential details of a practical cavity maser system are described.

621.375.9:538.569.4 1164

Maser Operation with Signal Frequency Higher than Pump Frequency—F. R. Arams. (PROC. IRE, vol. 48, p. 108; January, 1960.) An X-band solid-state maser is described using the four Zeeman levels in ruby.

621.375.9:538.569.4 1165

Investigation of the Oscillation Voltage of a Strong-Field Maser-Type Self-Oscillator—H. Benoit and C. Fric. (*Compt. rend.*, vol. 249, pp. 537–539; July 27, 1959.) Investigation of a maser of the type described earlier (798 of March) in which the macroscopic polarization of the protons is made antiparallel to the directive field. Experimental and theoretical E/Q curves are shown for different rates of flow.

621.375.9:621.372.44 1166

Experimental Verification of Parametric-Amplifier Excess Noise using Transformer Coupling—S. Cohen. (PROC. IRE, vol. 48, pp. 108–109; January, 1960.) A method is described for measuring noise temperature at frequencies where circulators are not available.

621.375.9:621.372.44:621.372.2 1167

An Analysis of Parametric Amplification in Periodically Loaded Transmission Lines—G. H. Heilmeier. (*RCA Rev.*, vol. 20, pp. 442–454; September, 1959.) The propagating structure is considered as a lossless transmission line periodically loaded with nonlinear capacitance in the form of back-biased semiconductor diodes. Information is given about the relation of diode parameters, spacing and circuit parameters to the gain and bandwidth of the structure.

621.375.9:621.372.44:621.385.63 1168

Fast-Wave Couplers for Longitudinal-Beam Parametric Amplifiers—Ashkin, Louisell, and Quate. (*See* 1449.)

621.375.9:621.376.029.65 1169

Three-Level Maser Detector for Ultra Microwaves—K. Shimoda (*J. Phys. Soc. Japan*, vol. 14, p. 966; July, 1959.) Note on the principles of a device similar to the spectrometer described earlier (*see* 1355 below). The absorption at ultramicrowave frequencies changes the population of levels and results in an increase or decrease of absorption at a lower microwave frequency.

621.375.9.121.2:621.372.44 1170

Mode Theory of Lossless Periodically Distributed Parametric Amplifiers—K. Kurokawa and J. Hamasaki. (TRANS. IRE ON MICROWAVE THEORY AND TECHNIQUES, vol. MTT-7, pp. 360–365; July, 1969. Abstract, PROC. IRE, vol. 47, p. 1796; October, 1959.)

621.376.32:621.382.3 1171

Reactance Transistor—Y. Fujimura and N. Mii. (PROC. IRE, vol. 48, p. 118; January, 1960.) Frequency deviation curves calculated from the theoretical output admittance are compared with measurements for a given FM oscillator circuit.

GENERAL PHYSICS

53.081.6 1172

On Explanations of Electric and Magnetic Constants and Units—A. T. Gresky. (*J. Franklin Inst.*, vol. 267, pp. 201–210; March, 1959.) Using dimensional methods, the relation of free-space dielectric constant, and magnetic permeability constant to four fundamental quantities is considered. Other constants are also analyzed to obtain methods of understanding the submicroscopic nature of electric and magnetic phenomena. See also 3752 of 1958.

537.311.1 1173

Variational Approach to Deviations from Ohm's Law—I. Adawi. (*Phys. Rev.*, vol. 115, pp. 1152–1156; September 1, 1959.) Kohler's variational method has been used to obtain deviations from Ohm's law for a nondegenerate electron gas. Two important applications of the method are discussed.

537.311.33 1174

Many-Particle Approach to the One-Electron Problem of Insulators and Semiconductors—A. Klein. (*Phys. Rev.*, vol. 115, pp. 1136–1146; September 1, 1959.) Motion of an electron near the bottom of the conduction band in the presence of external electric and magnetic fields, whose variation over one lattice spacing is small, is governed by a simple Schrödinger equation.

537.312.8 1175

Energy Levels of Conduction Electrons in a Magnetic Field—Y. Yafet. (*Phys. Rev.*, vol. 115, pp. 1172–1176; September, 1959.) The energy levels can be obtained simply if the spherical approximation is made for the band structure. The free energy due to small departures from this assumption may be estimated using perturbation theory. Inclusion of spin-orbit coupling gives the g factor as a function of position in the band.

537.525 1176

The Current Sheet in a Gas Discharge—N. J. Phillips. (*Proc. Phys. Soc.* (*London*), vol. 74, pp. 700–704; December 1, 1959.) Deals with the trapping of cold gas in the sheet.

537.525:538.63 1177

Studies of Cold-Cathode Discharges in Magnetic Fields—J. Backus. (*J. Appl. Phys.*, vol. 30, pp. 1866–1869; December, 1959.) The current is 75 per cent ionic. Mass-spectrometer measurements were made to determine the ion energies. The mechanism of the discharge is discussed.

537.533.8 1178

Theory of Secondary Electron Emission of Metals: the Excitation Process—H. W. Streitwolf. [*Ann. Phys.*, (*Lpz.*), vol. 3, pp. 183–196; March 24, 1959.] See also 1179 below and 3757 of 1959 (Stolz & Streitwolf).

537.533.8 1179

Theory of Secondary Electron Emission of Metals: the Transport Process—H. Stolz. [*Ann. Phys.*, (*Lpz.*), vol. 3, pp. 197–210; March 24, 1959.]

537.56 1180

Conductivity of a Warm Plasma—L. Mower (*Phys. Rev.*, vol. 116, pp. 16–18; October 1, 1959.) "A theory for obtaining the conductivity of a uniform plasma as a function of frequency and temperature is presented and compared with a number of recent treatments."

537.56 1181

Experiments with Plasma Rings—L. Lindberg, E. Witalis, and C. T. Jacobsen. (*Nature*, vol. 185, pp. 452–453; February 13, 1960.) A brief description is given of a plasma gun discharging into a glass drift tube. Measurements have been made of the circuit current and the magnetic flux carried by the plasma.

537.56:538.56 1182

Oscillations in Plasma: Part 2.—S. Kojima, K. Kato, S. Hagiwara, and R. Matsuzaki. (*J. Phys. Soc. Japan*, vol. 14, pp. 821–827; June, 1959.) Discrete oscillations reported in Part 1 (1699 of 1958) are studied in detail. Oscillations at the higher frequency are generated by the convergent beam in the central part of the tube, while those at the lower frequency seem to be generated near the wall of the tube by the divergent beam. Another oscillation having an intermediate frequency is often observed.

537.56:538.561 1183

Occurrence of Vavilov-Čerenkov Radiation in a High-Temperature Plasma—J. Neufeld. (*Phys. Rev.*, vol. 116, pp. 1–3; October 1, 1959.) Analytical results indicate that radiation is not emitted by a particle moving through a high-temperature plasma at a velocity lower than the mean thermal velocity of plasma electrons.

537.56:538.566 1184

Longitudinal and Transverse Waves in a Lorentz Plasma—K. Rawer and K. Suchy. [*Ann. Phys.* (*Lpz.*), vol. 3, pp. 155–170; March 24, 1959.] The triple refraction in inhomogeneous plasma is discussed. See also 3641 of 1959.

537.56:538.6 1185

Radial Hydromagnetic Oscillations—G. B. F. Niblett and T. S. Green [*Proc. Phys. Soc.* (*London*), vol. 74, pp. 737–743; December 1, 1959.] The equation of motion of radial hydromagnetic oscillations of a plasma confined by an axial magnetic field is integrated and shown to give good agreement with experiment.

537.56:538.63 1186

Discharge Phenomena in Lorentz-Type Plasmas: Investigation of Electron Distribution in the Presence of a Magnetic Field—P. Maroni. (*Compt. rend.*, vol. 249, pp. 881–883; August 24, 1959.) A partial differential equation derived by Kahan and Jancel (see 3453 of 1957 and back references) is integrated for the case where the collision frequency is constant. (For further discussion see *ibid.*, vol. 249, pp. 914–916; August 31, 1959.)

538.566:535.42]+534.26 1187

The Half-Plane Diffraction Problem for Harmonic Time Dependence—A. P. Burger. [*Proc. Roy. Soc.* (*London*), *A*., vol. 252, pp. 411–417; September 29, 1959.] "Green's functions are obtained for the boundary-value problems of mixed type describing the general two-dimensional diffraction problems at a screen in the form of a half-plane (Sommerfeld's problem), applicable to acoustically rigid or soft screens, and to the full electromagnetic field at a perfectly conducting screen."

538.566:535.42 1188

The Diffraction of Scalar Waves on Paraboloids of Revolution—K. Klante. [*Ann. Phys.* (*Lpz.*), vol. 3, pp. 171–182; March 24, 1959.]

538.566:535.42 1189

Diffraction by an Imperfectly Conducting Right-Angled Wedge—W. E. Williams. (*Proc. Camb. Phil. Soc.*, vol. 55, Part 2, pp. 195–209; April, 1959.) An exact solution is given for the diffraction of the field of an electric line current by an imperfectly conducting wedge of exterior angle $3\pi:2$.

538.566:535.42 1190

Diffraction of an E-Polarized Plane Wave by an Imperfectly Conducting Wedge—W. E. Williams. [*Proc. Roy. Soc.* (*London*) *A*, vol. 252, pp. 376–393; September 29, 1959.] A new and exact solution is obtained for arbitrary wedge angle.

538.566:538.6 1191

Propagation of Electromagnetic Waves in a Multistream Medium at Gyromagnetic Resonance—J. Neufeld. (*Phys. Rev.*, vol. 116, pp. 19–20; October 1, 1959.) Formulas are derived for the dispersion and the gyromagnetic resonance effects.

538.569.4 1192

Measurement Broadening in Magnetic Resonance—O. E. Myers and E. J. Putzer. (*J. Appl. Phys.*, vol. 30, pp. 1987–1991; December, 1959.) Phase-detection techniques cause broadening: a method for correcting observed widths is described.

538.652 1193

Form Effect in Magnetostriction—R. Gersdorf. (*J. Appl. Phys.*, vol. 30, pp. 2018–2019; December, 1959.) Comment on 2930 of 1959 (Stauss).

539.2:537.311.33:537.52 1194

A Simplified Theory of Two-Carrier, Space-Change-Limited Current Flow in Solids—M. A. Lampert. (*RCA Rev.*, vol. 20, pp. 682–701; December, 1959.)

539.2:538.222 1195

Zeeman Splitting of Paramagnetic Atoms in Crystalline Fields—H. Statz and G. F. Koster. (*Phys. Rev.*, vol. 115, pp. 1568–1577; September 15, 1959.) Energy levels of paramagnetic ions in crystalline surroundings are treated as a function of magnetic field.

539.2:538.6 1196

Theory of Block Electrons in a Magnetic Field: the Effective Hamiltonian—W. Kohn. (*Phys. Rev.*, vol. 115, pp. 1460–1478; September 15, 1959.) For a nondegenerate band the eigenstates of the Hamiltonian of a Block electron in a static magnetic field can be calculated from an equivalent Hamiltonian whose properties and formulation are discussed.

GEOPHYSICAL AND EXTRATERRESTRIAL PHENOMENA

523.152:629.19:061.3 1197

Symposium on the Exploration of Space—(*J. Geophys. Res.*, vol. 64, pp. 1647–1800; November, 1959.) The text is given with subsequent discussion of twelve papers read at a symposium in Washington, D. C., April 29–30, 1959.

523.164 1198

National Radio Astronomy Observatory—R. M. Emberson. (*Science*, vol. 130, pp. 1307–1318; November 13, 1959.) The history and development of the radio observatory at Green Bank, W. Va., are reviewed.

523.164 1199

The Mullard Radio Astronomy Observatory—M. Pyle. (*J. IEE*, vol. 6, pp. 14–19; January, 1960.) Two aperture-synthesis radio telescopes installed near Cambridge, Eng., are described and an outline is given of the present research program.

523.164:621.396.677.833 1200

The 600-Foot Radio Telescope—E. F. McClain, Jr. (*Sci. Amer.*, vol. 202, pp. 45–51; January, 1960.) Description of the steerable telescope under construction in West Virginia.

523.164.32:523.78 1201

Observations on the Solar Eclipse of October 2—J. Aarons, J. P. Castelli, R. M. Straka, and W. C. Kidd. (*Nature*, vol. 185, pp. 230–231; January 23, 1960.) A report of measurements made simultaneously on 224, 1300 and 3000 mc at Hamilton, Mass., in 1959. At this location the sun rose partially eclipsed and was totally eclipsed at an elevation of about 1 degree.
